ASX ANNOUNCEMENT

7 July 2026

EVR Defines 1.1km High-Grade Antimony-Gold Target in Soils at Nevada Project

Highlights

- **Two Structurally Controlled Systems Confirmed:** Maiden soil geochemistry at Milton and Dollar has defined coherent, structurally controlled mineral corridors directly overlying historic mine workings.
- **1,100m Milton Corridor Delineated:** Geochemical fingerprinting has identified a highly coherent, **1,100m-long continuous anomalous pathfinder corridor** (Au-As-Sb-Hg-Tl) directly matching mapped north-south jasperoid trends.
- **Dollar Project – Zoned Antimony Systems:** High-resolution sampling has mapped two mineralised systems, representing a zoned hydrothermal system with mineralised zones each anchored to historic production locations:
    - **Dollar Mine Node:** High-grade Gold-Arsenic-Antimony system in the north with soil peaks up to **0.415 ppm Au** and **2,080 ppm Sb**.
    - **Resurrection Node:** Distinct high-amplitude Silver-Lead-Zinc polymetallic system in the south yielding up to **17.05 ppm Ag**, **872 ppm Pb**, and **2,680 ppm Zn**.
- **Zonation Model Identified:** Geochemical signatures at Dollar point to a high-potential 200m–300m strike zonation, indicating an extensive, structurally controlled hydrothermal system.
- **New Copper Target Materialising:** Surface exploration confirms a previously unrecognised copper-oxide breccia structure in the Dollar tenement's southeastern block, adding further exploration upside.
- **Clear Path to Drill Target Definition:** Rock-chip sampling and a potential geophysical survey are being planned over the coming months to convert the defined corridors into a maiden scout drilling program at both projects.

EV Resources Limited (ASX:EVR) ("**EVR**", the "**Company**") is pleased to announce results from its maiden, high-density, multi-element soil geochemistry program at the 100%-owned Milton and Dollar Projects in Nye County, Nevada, USA (see Figure 6).

The results have defined coherent, **structurally controlled mineral corridors at both projects, giving EVR its first systematic target areas for further exploration across its US antimony portfolio** and a clear pathway toward future drill testing. The findings reinforce EVR's dual-track strategy of targeting **near-term production in Mexico alongside a growing domestic US antimony supply position,** a thematic gaining urgency amid tightening Western supply chains.

The systematic survey, completed by specialty consultants Frontfinders Exploration, comprised 567 soil samples (324 at Milton, 243 at Dollar) grid-spaced at 100m lines with 25m stations targeting C-horizon residual regolith. The analytical data, processed via ALS Laboratories' comprehensive 50-element AuME-TL43 aqua regia package, has passed

rigorous QA/QC inspection and successfully mapped walk-up exploration targets at both projects.

Managing Director and CEO, Mike Brown, commented: *"The multi-element soil geochemistry results give us a clear, data-driven framework for our next phase of exploration at Milton and Dollar. The high-density grid sampling has delineated tightly constrained, structurally controlled corridors that line up directly with our reconnaissance geological mapping and historic working boundaries.*

At Milton, we have confirmed a clean gold-antimony pathfinder suite that validates our structural model and introduces thallium as a highly effective localised vectoring tool. At Dollar, we have mapped separate gold-antimony and silver-polymetallic systems consistent with a zoned hydrothermal system with multiple mineralised targets. These geochemical footprints establish a strong technical foundation as we advance our mapping, initiate geophysical surveys, and systematically refine our targets for potential drill testing.

Elevated antimony across both projects is highly meaningful in the current US domestic antimony deficit. Establishing non-reliance on sensitive, highly strategic supply chains makes secure jurisdictions like Nevada a priority for Western markets".

Milton Project: Structure-Controlled Antimony-Gold System Confirmed

Geological field reconnaissance at Milton confirmed extensive hydrothermal silicification and prominent brown-to-reddish jasperoid replacement bodies running along a primary north-south structural conduit within reactive Triassic Luning Formation carbonates. Sample spacing was tightened to 25m to reflect antimony's limited mobility in soil.

Multi-element assay data provides strong geochemical validation of this structural corridor. Statistical Spearman correlation identifies Milton as an exceptionally clean, low base-metal Au-As-Sb-Hg-Tl mineral system, consistent with a Carlin-style or classic epithermal hydrothermal setting. See Appendix A for full table of results.

Advanced Pathfinder Mapping

The dataset highlights a premium multi-element target population where 22 standalone samples sit within the highest 90th percentile decile for all five classic hydrothermal and Carlin-style pathfinder elements simultaneously. This has defined a high-confidence **1,100m continuous anomalous** corridor along a visually mapped jasperoid trend (see Figure 1).

- **Thallium (Tl) Vector:** Thallium is the strongest pathfinder pairing in the district, with a Sb-Tl correlation coefficient of r=0.82. Peak node sample M-190 carried the highest Tl value in the dataset at **2.45 ppm Tl** (P90 threshold 0.73 ppm) alongside a strong gold response of **0.118 ppm Au**.
- **Discrete High-Grade Node:** Sample M-162 returned **5.44 ppm mercury (Hg)** (roughly 30x the dataset median) and elevated Copper (Cu) alongside strong Sb of **121.5 ppm**, pointing to an immediate sub-surface structural trap or blowout zone warranting further follow-up rock-chip sampling.

Field observations at Milton confirmed a structurally controlled hydrothermal alteration system within carbonate-rich stratigraphy, characterised by:

- Intensive silicification;
- Well-developed jasperoid bodies;
- North-south structural control;
- Carbonate-hosted alteration; and
- Quartz veining.

The jasperoid zones are interpreted to represent hydrothermal replacement of carbonate host rocks along deep-seated structures. These structures likely served as channels for mineralising fluids and are therefore considered high-priority targets for systematic rock chip sampling and follow up exploration.

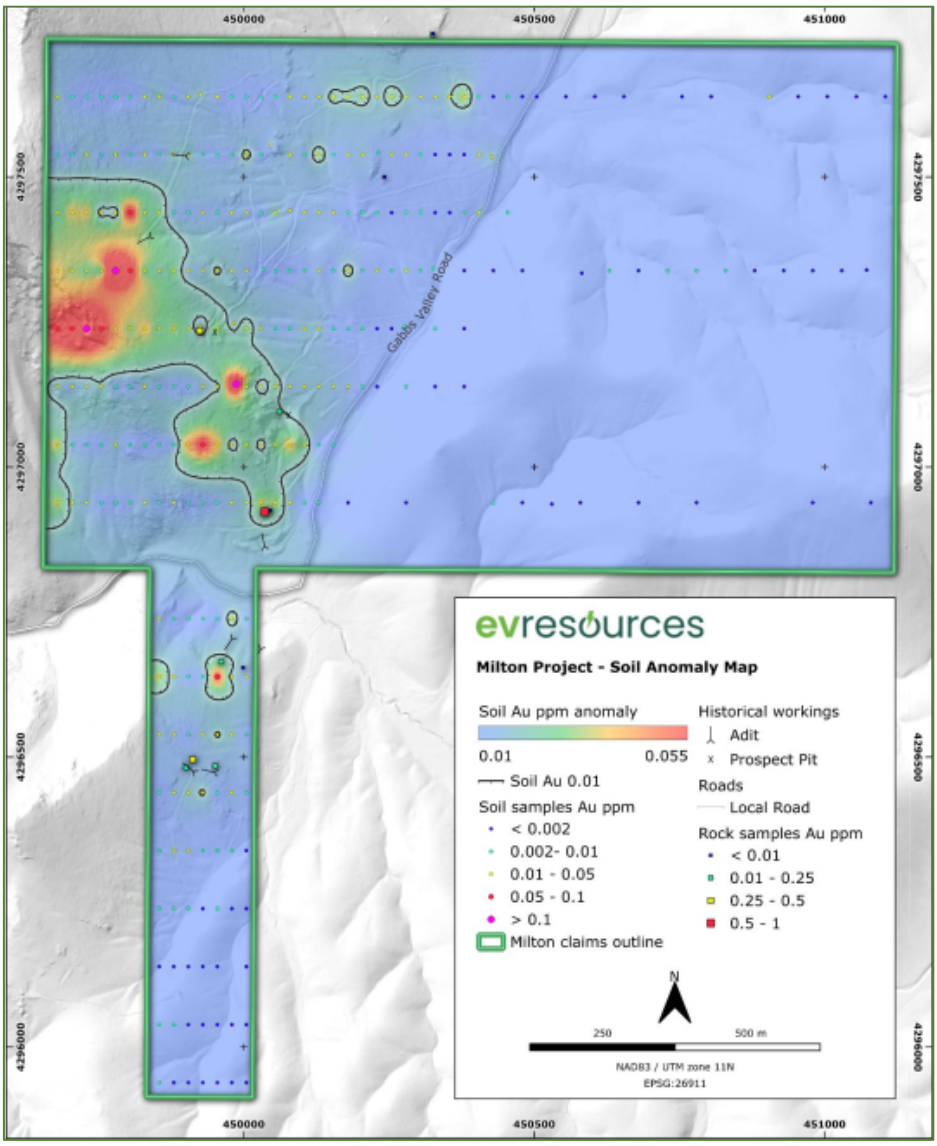

Figure 2: Milton Project – Soil Anomaly Map – Gold (Au ppm) and Previously Reported Rock chip Results

Dollar Project: Two Distinct Mineralised Systems Defined, Pointing to a Telescoped Hydrothermal System

The local geology at Dollar exhibits a more complex sedimentary-volcanic-intrusive environment. Multi-element data sets separate the property into two independent, premium target populations, each anchored to a key historic mine footprint. See Appendix B for full table of results.

1. The Dollar Mine Node - Gold-Antimony System

Characterised by elevated gold and arsenic with low base-metal signatures, sitting directly over historic Dollar Mine surface structures.

- **Sample D-094:** Returned very high absolute peak anomalies of **0.415 ppm Au** and a massive **2,080 ppm Sb (0.2% Antimony)**.
- **Sample D-189:** Extended the system footprint with an impressive **1,305 ppm As** and **0.167 ppm Au** response.

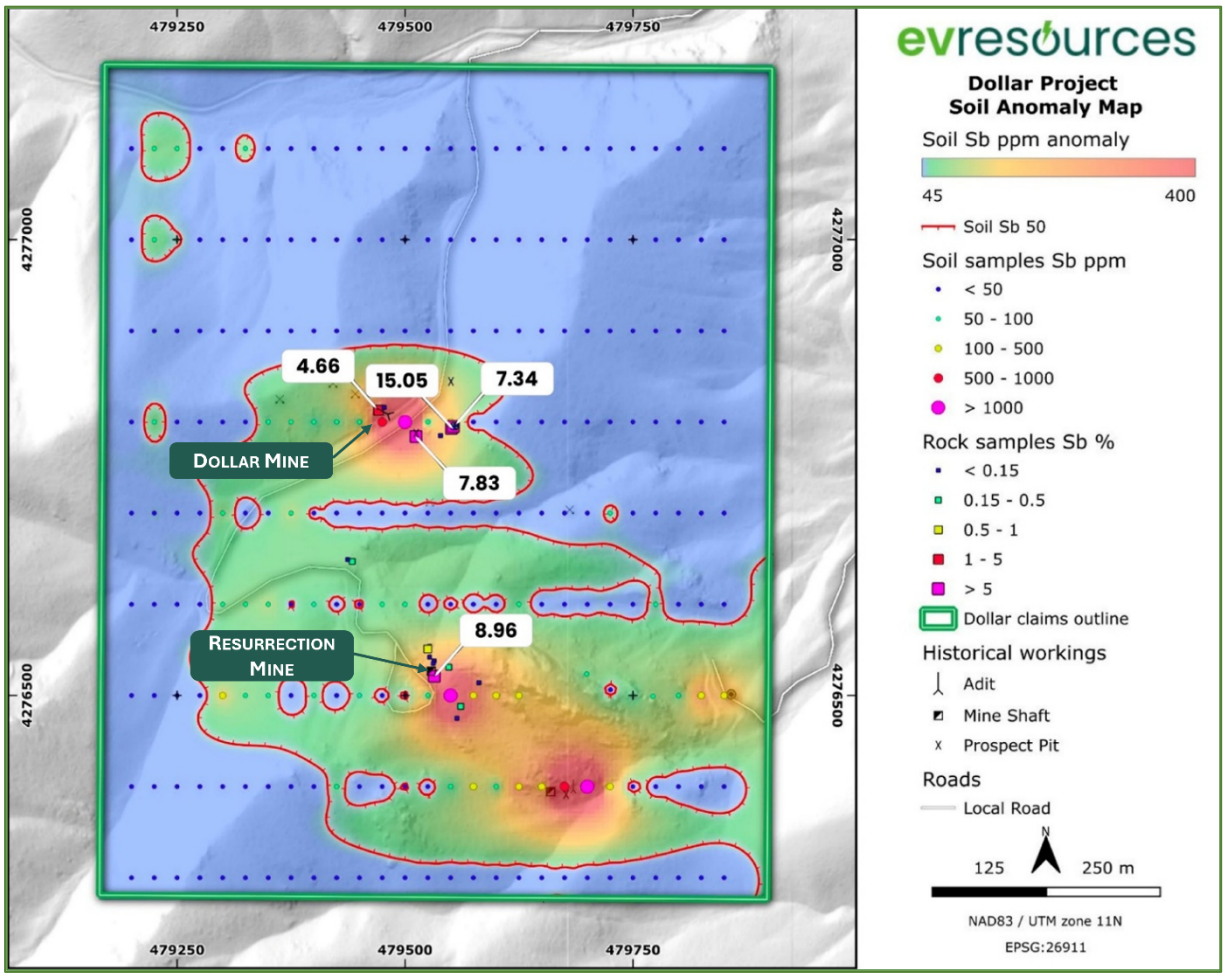

Figure 3: Dollar Project – Soil Anomaly Map- **Antimony (ppm Sb)** and Previously Reported Rock chip Results

2. The Resurrection Node - Polymetallic Silver-Base Metal System

Located approximately 200m south, near historic shaft PB39, this zone displays a distinct silver-lead-zinc polymetallic signature, spatially separated from the gold-antimony population by ~200m of strike.

- **Sample D-209:** Returned **17.05 ppm Ag** (highest Ag in the Dollar dataset) paired with **932 ppm Sb** and **872 ppm Pb**, anchoring the polymetallic assemblage at the Resurrection historic workings.
- **Sample D-210:** Yielded a highly anomalous **2,680 ppm Zn**, the highest zinc value in the Dollar population, validating the silver-lead-zinc zonation model.

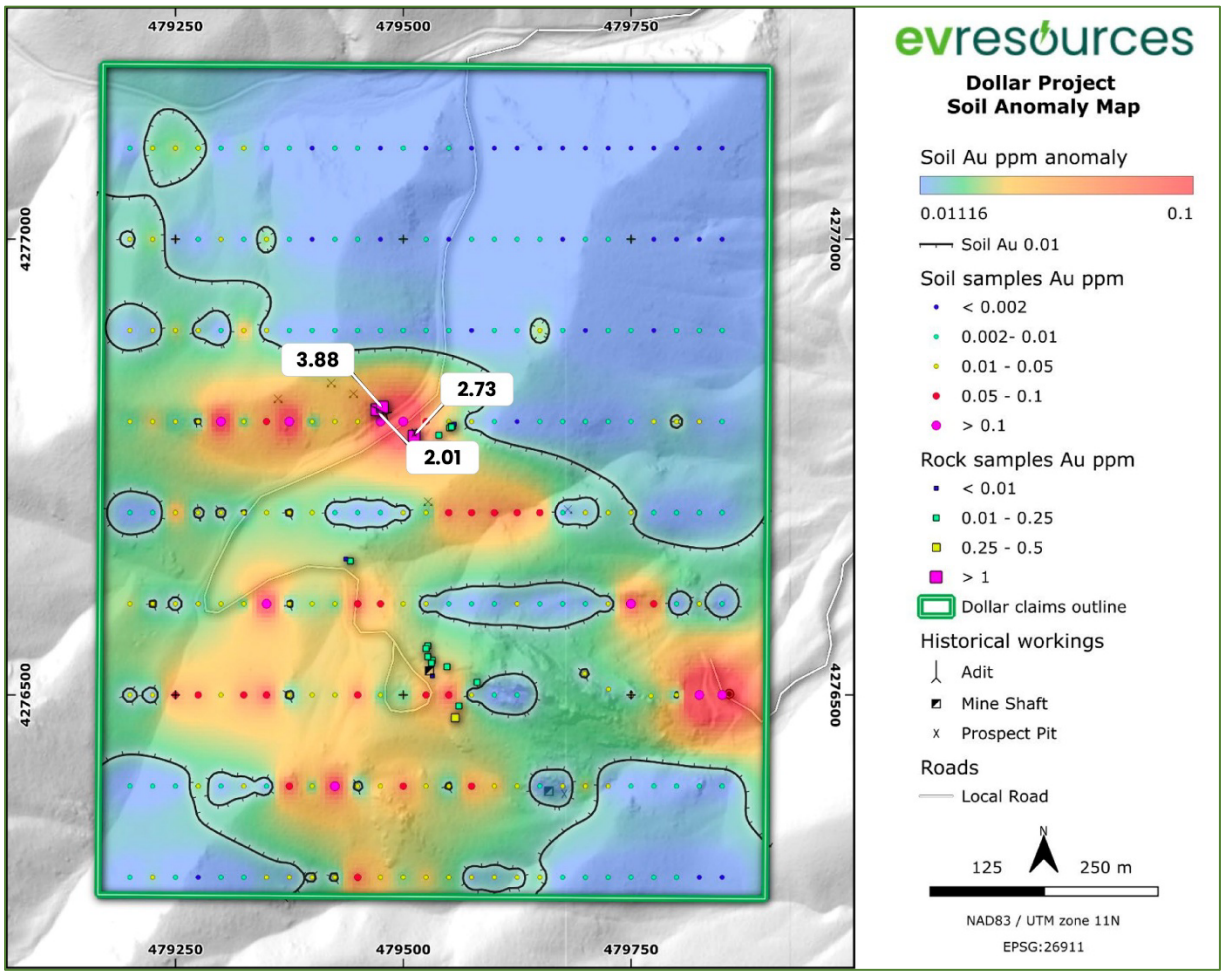

Figure 4: Dollar Project – Soil Anomaly Map- **Gold (Au ppm)** and Previously Reported Rock chip Results

Exploration Significance: The Telescoping Model

EVR's technical team interprets this spatial distribution at Dollar as a classic vertical/lateral hydrothermal telescoping zonation model. The polymetallic Ag-Pb-Zn-Sb assemblage in the south transitions cleanly into a high-temperature Au-As-Sb structural corridor over a 300m strike vector to the north.

This interpretation is supported by the strong Sb-Au correlation (r=0.76) but weak Ag-Au correlation (r=0.15), indicating two largely independent geochemical associations co-occurring within the same soil grid. The latter suggests a significant single fluid pathway that remains open for further testing and will be refined through follow-up sampling and geophysics.

New Southeastern Copper Target Identified at Dollar

In addition to the defined zonation pathways, field mapping has successfully identified a previously unrecognised, unmined north-south trending structural corridor near the eastern block of the Dollar tenement marked by outcropping heavily silicified and weathered breccia hosting visible secondary copper-oxide mineralisation (see Figure 5).

The copper overprinting was observed along a structure trending broadly parallel to the eastern tenement boundary and is considered a priority follow-up target, potentially indicative of a deeper mineralising system distinct from the antimony-silver-gold assemblages.

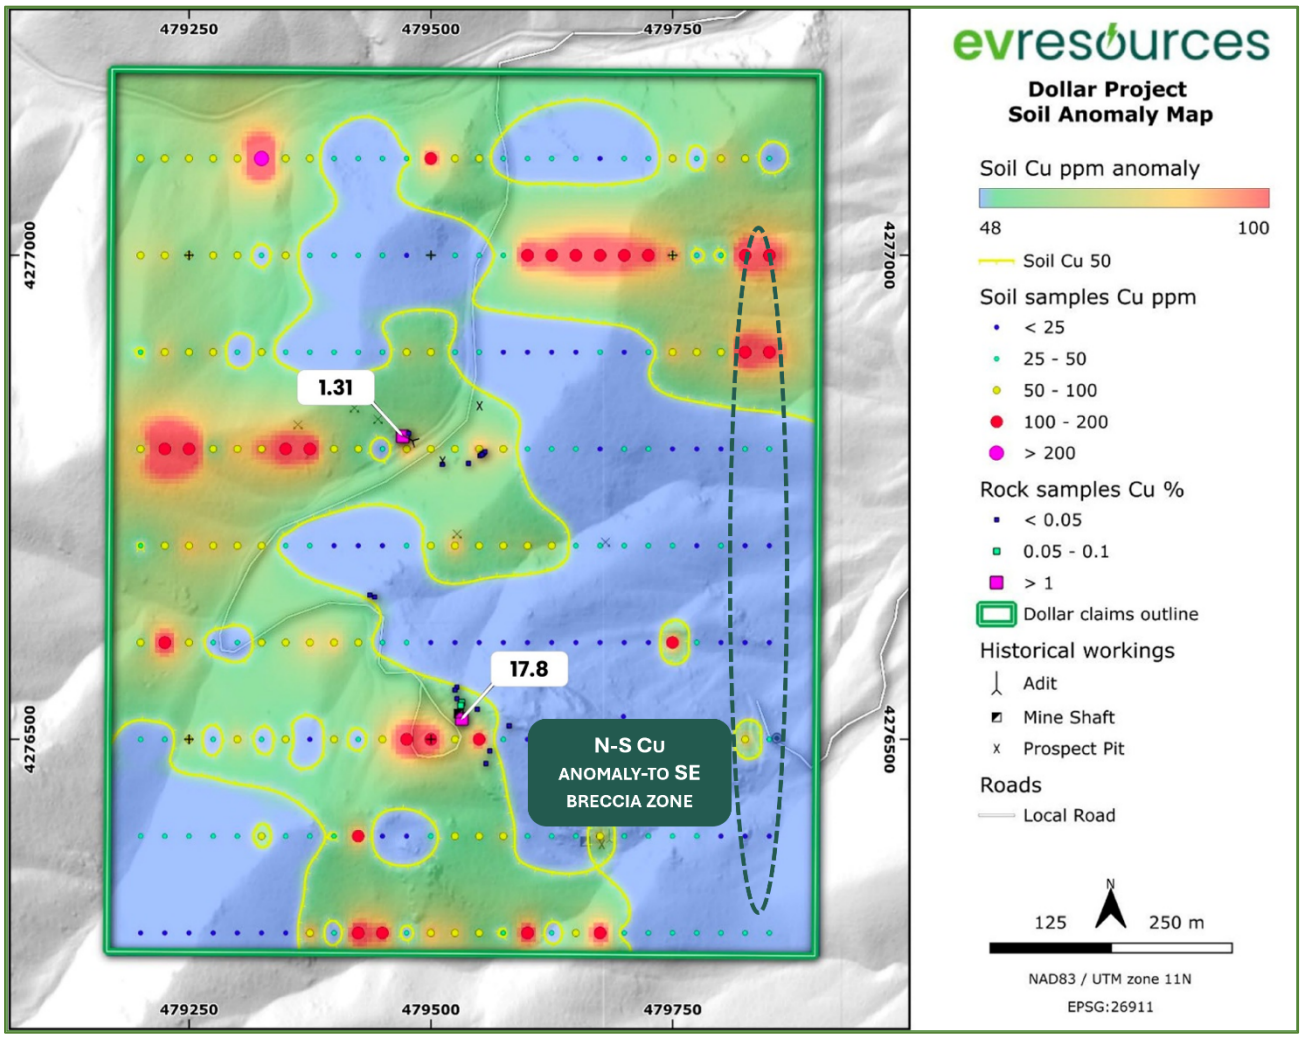

Figure 5: Dollar Project – Newly Identified Copper-Oxide Breccia Target and Previously Reported Rock chip Results

Next Steps & Forward Exploration Strategy

With high-confidence structural targets now mathematically and geologically locked in, EV Resources will advance fieldwork to transition these anomalies into firm drill targets:

1. **Focused Structural Rock-Chip Sampling:** Immediate deployment of field teams to conduct high-density channel and rock-chip sampling directly across the exposed jasperoid ridges at Milton and the copper breccias at Dollar.
2. **Ground Geophysics:** Review of geophysical technologies for appropriateness and costing for high-resolution electrical geophysical surveys (Induced Polarisation / Resistivity) across the 1.1km Milton jasperoid trend to locate fluid conduits, faults, and sulphide concentrations at depth.
3. **Drill Target Generation:** Synthesis of historical data with the new soil footprints and forthcoming geophysics to build out a robust, prioritized maiden diamond/RC drilling campaign.

Compliance Statement

The information in this announcement that relates to new Exploration Results (specifically soil geochemistry and surface geological mapping at the Milton and Dollar Projects) is based on, and fairly represents, data and compiled documentation prepared by Frontfinders Exploration and reviewed by Mr. Mike Brown.

This announcement contains exploration results extracted from ASX market announcements dated 27 January 2026 and 28 January 2026, and reported in accordance with the 2012 edition of the “Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves” ("2012 JORC Code"). The competent person for the announcements was Mr Mike Brown. EVR confirms that

it is not aware of any new information or data that materially affects the information included in the original ASX market announcement. The Company confirms that the form and context in which the Competent Person's findings are presented have not been materially modified from the original market announcement.

Competent Person Statement

Information in this announcement that relates to the collection and reporting of Exploration Results is based on information collected and compiled by Frontfinders Exploration, an experienced and suitably qualified independent Company, and reviewed and by Mr Mike Brown, a Competent Person who is a member of the Australian Institute of Geoscientists. Mr Brown is the Managing Director and CEO of EVR. Mr Brown has sufficient experience relevant to the style of mineralisation, and the activity undertaken to qualify as a Competent Person, as defined by the Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves (The JORC Code) 2012 Edition. Mr Brown consents to the inclusion in this announcement of the matters based on the exploration results in the form and context in which they appear.

Forward Looking Statements

Forward Looking Statements regarding EVR´s plans with respect to its mineral properties and programs are statements that are not historical facts. Words such as "expect(s)", "feel(s)", "believe(s)", "will", "may", "anticipate(s)", "potential(s)"and similar expressions are intended to identify forward-looking statements. These statements include, but are not limited to statements regarding future production, resources or reserves and exploration results. All of such statements are subject to certain risks and uncertainties, many of which are difficult to predict and generally beyond the control of the company, that could cause actual results to differ materially from those expressed in, or implied or projected by, the forward-looking information and statements. There can be no assurance that EVR's plans for development of its mineral properties will proceed as currently expected. There can also be no assurance that EVR will be able to confirm the presence of additional mineral resources, that any mineralisation will prove to be economic or that a mine will successfully be developed on any of EVR's mineral properties. The performance of EVR may be influenced by a number of factors which are outside the control of the Company and its Directors, staff, and contractors.

These risks and uncertainties include, but are not limited to: (i) those relating to the interpretation of drill results, the geology, grade and continuity of mineral deposits and conclusions of economic evaluations, (ii) risks relating to possible variations in reserves, grade, planned mining dilution and ore loss, or recovery rates and changes in project parameters as plans continue to be refined, (iii) the potential for delays in exploration or development activities or the completion of feasibility studies, (iv) risks related to commodity price and foreign exchange rate fluctuations, (v) risks related to failure to obtain adequate financing on a timely basis and on acceptable terms or delays in obtaining governmental approvals or in the completion of development or construction activities, and (vi) other risks and uncertainties related to the company's prospects, properties and business strategy. Our audience is cautioned not to place undue reliance on these forward-looking statements that speak only as of the date hereof, and we do not undertake any obligation to revise and disseminate forward-looking statements to reflect events or circumstances after the date hereof, or to reflect the occurrence of or non-occurrence of any events.

About EV Resources

EV Resources (ASX: EVR) is a critical minerals exploration and development company focused on securing the North American antimony supply chain.

We are rapidly transitioning from a diversified explorer to an expected near-term antimony producer. Antimony is a designated critical mineral by the US, EU, and Australia, with applications in energy storage, battery technology, defence, and high-tech applications.
Our asset portfolio is strategically positioned in mining-friendly jurisdictions:

- **Tecomatlán Processing Plant**, **(Mexico).** Targeting a near term low CAPEX path to becoming an antimony producer. Refurbishment and installing a gravitational concentrator circuit is underway, providing a low cost highly efficient processing path for antimony, initially processing 3rd party sourced ore and eventually Los Lirios material.
- **Los Lirios Antimony Project (Mexico):** Our flagship, high-grade antimony project, 50km from the Tecomatlán plant. First-pass drilling has confirmed a laterally extensive CRD system, with advancement towards a maiden JORC Resource delineation underway.
- **US Antimony Projects - Dollar and Milton (Nevada):** 100%-owned assets strategically positioned to support the US domestic critical minerals supply chain, aligned with US government antimony designation priorities.

JORC Code, 2012 Edition – Table 1 Report

Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections)

Criteria	JORC Code Explanation	Commentary

Sampling techniques	• *Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.*
	• *Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.*
	• *Aspects of the determination of mineralisation that are Material to the Public Report*
	• *In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information*
		• Across much of the Milton and Dollar project areas, soil development is limited due to steep topography, active erosion, shallow bedrock, and locally extensive colluvial cover.
		• A and B soil horizons are generally absent or poorly developed. Sampling therefore targeted the C-horizon, consisting of residual and colluvial regolith material where present.
		• At each station, loose surficial material was removed prior to sample collection. Samples were generally collected from a few centimetres below surface, and locally from depths of up to approximately 10 cm where C-horizon material was more developed.
		The workflow included:
		  • Removal of coarse fragments and organic debris;
		  • Dry sieving to <2 mm;
		  • Manual homogenisation of the <2 mm fraction in a clean container;
		  • Placement of homogenised material into labelled zip-lock sample bag;
		  • Field recording and sample sequence verification.
		  • Dry sieving to <2 mm was undertaken to reduce the influence of coarse clasts and improve consistency between samples
		• Channels were between 50cm to 100cm long,

Criteria	JORC Code Explanation	Commentary
		10cm wide, and 3cm deep. Surfaces were cleaned. The channels were sampled on a continuous basis. • The samples were collected and bagged and labelled.
Drilling techniques	• *Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face- sampling bit or other type, whether core is oriented and if so, by what method, etc).*	• No drilling was undertaken.
Drill sample recovery	• *Method of recording and assessing core and chip sample recoveries and results assessed.* • *Measures taken to maximise sample recovery and ensure representative nature of the samples.* • *Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.*	• No drilling was undertaken.
Logging	• *Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.* • *Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.* • *The total length and percentage of the relevant intersections logged.*	• Sampling horizon was logged, including any observed man made features (roads, adits). As per above horizon C was sampled due to lack of development of B horizon. • Not applicable for soil sampling • Not applicable for soil sampling

Criteria	JORC Code Explanation	Commentary
Sub- sampling techniques and sample preparation	• *If core, whether cut or sawn and whether quarter, half or all cores taken.* • *If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.* • *For all sample types, the nature, quality and appropriateness of the sample preparation technique.* • *Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.* • *Measures taken to ensure that the sampling is representative of the in-situ material collected, including for instance results for field duplicate/second-half sampling.* • *Whether sample sizes are appropriate to the grain size of the material being sampled.*	• Sample from hand dug hole was dry sieved to <2mm and bagged. • A blank and a standard were inserted as per Company QA/QC protocol.

Quality of assay data and laboratory tests	• *The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.*
	• *For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.*
	• *Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.*
		• Samples selected for laboratory analysis were prepared for shipment with documented chain of custody. Sample transport and submission procedures followed standard industry practice.
		• Soil samples were prepared at ALS Global using the PREP-41 protocol, which includes:
		  • drying of samples,
		  • sieving to <180 microns, and
		  • homogenisation of the fine fraction prior to analysis.
		• Prepared soil samples will be analysed by ALS Laboratories using method AuME-TL43. This method uses aqua regia digestion, with gold and a multi-element suite determined from the resulting solution by a combination of ICP-MS and ICP-AES.

Criteria	JORC Code Explanation	Commentary
		• The company has a QA/QC protocol that requires insertion of blanks every 20 samples and one CRM standard. (OREAS508, 21f,and 232b) was the standard submitted to the Laboratory based on its polymetallic nature. • The laboratory has their own certified QA/QC procedures including equipment calibration. • QA/QC review of assays results against CRMs, duplicates and blanks was undertaken. • The QA/QC data for the Dollar and Milton soil geochemistry submissions are considered acceptable and fit for purpose. Accuracy (CRMs), precision (duplicates) and contamination (blanks) have each been assessed; all are within expected limits, with only minor, non-material 2SD warnings on individual standards. The data are considered suitable for use in target generation and ongoing exploration
Verification of sampling and assaying	• *The verification of significant intersections by either independent or alternative company personnel.* • *The use of twinned holes.* • *Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.* • *Discuss any adjustment to assay data*	• Not applicable as no drilling was undertaken. • Not applicable as no drilling was undertaken. • Not fully applicable-assays were received from laboratory, entered into database and reviewed, with subsequent QA/QC analysis undertaken. • No data adjustments were applied.
	• *Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.*	• Sample locations were recorded using handheld GPS units loaded with pre-prepared KMZ files. • Pre-printed soil sampling maps were used in the field to provide: • Topographic awareness;

Criteria	JORC Code Explanation	Commentary
Location of data points	• *Specification of the grid system used.* • *Quality and adequacy of topographic control.*	• Planned sample station control; • Traverse orientation; • Geological context; • Improved field navigation • The grid system employed was the UTM coordinate system (NA83-UTMZone11) which provided a spatial framework considered reliable for initial exploration activity. Coordinates logged in the assay database. • Topographic control was considered adequate, based on reference to regional topographic maps and confirmed by site observations.

Data spacing and distribution	• *Data spacing for reporting of Exploration Results.*
	• *Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.*
	• *Whether sample compositing has been applied.*
		• Soil samples were collected along parallel profile lines. The standard sampling design comprised:
		  • ¬ Profile line spacing of approximately 100 m;
		  • ¬ Sample spacing of 25 m along profile lines.
		• In the eastern portion of the Milton Project, profile line spacing was increased to approximately 400 m due to volcanic cover. Sampling stations also increased to 50 m intervals along the profile lines to the east over volcanic cover.
		• The sampling design was intended to detect geochemical dispersion associated with structurally controlled mineralisation while maintaining sufficient spatial resolution for follow up target definition Data is insufficient for resource estimation.
		• No compositing was applied.

Criteria	JORC Code Explanation	Commentary
Orientation of data in relation to geological structure	• *Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.* • *If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.*	• Samples collected perpendicular to the interpreted structural controls observed in historical workings, or stratigraphy for stratabound targets, minimizing bias. • Due to close nature of sample spacing (25m) sampling bias should be eliminated due to data density-although insufficient work has been done at the Projects to confirm this. • Not applicable as no drilling was undertaken
Sample security	• *The measures taken to ensure sample security.*	• Samples were bagged, tagged, labelled and secured on site, and were dispatched by secure transport with accompanying documentation, including the sample ID, location and description. This was verified upon receipt at the laboratory. The ALS laboratory has sample security and integrity processes in place.. • Tamper proof seals were used on all sample bags. All samples remained in the possession of the sampler.
Audits or reviews	• *The results of any audits or reviews of sampling techniques and data.*	No audits or reviews of sampling techniques and data were completed.

Section 2 Reporting of Exploration Results

(Criteria listed in the preceding section also apply to this section)

Criteria	JORC Code Explanation	Commentary

Mineral tenement and land tenure status	• *Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.*
	• *The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.*
		• The Milton claims are located in Nye County, Nevada. They are 100% owned by Strategic Metals Inc, a 100% owned Delaware incorporated US Subco of EV Resources Limited.
		• The project consists of 18 unpatented claim blocks with no known patented claims within them. Each claims block measures 1500ft north-south and 600ft east-west.
		• MA-1 to 18
		• The claims lie within the Humboldt-Toiyabe National Forest, administered by the US Forest Service (USFS).
		• There is a 2% NSR retained by the vendor (see ASX release, 26 Sept 2025), and no known impediments to obtaining a licence to operate in the area.
		Dollar Project:
		• The Dollar claims are located in Nye County, Nevada. They are 100% owned by EV Resources Limited through its subsidiary, Strategic Minerals Inc
		• The project consists of 8 unpatented claim blocks with no patented claims within them. Each claims block measures 1500ft north-south and 600ft east-west. The LEAD FILE NUMBER is: NV106750240
		  • DOLR 1
		  • DOLR 2
		  • DOLR 3
		  • DOLR 4
		  • DOLR 5
		  • DOLR 6

		• DOLR 7 • DOLR 8 • The claims lie within the Humboldt-Toiyabe National Forest, administered by the US Forest Service (USFS). There is a 2% NSR retained by the vendor (see ASX release, 10 Sept 2025), and no known impediments to obtaining a licence to operate in the area.
Exploration done by other parties	• *Acknowledgment and appraisal of exploration by other parties.*	Milton • The licences have been subjected to small to moderate scale underground mining over more than 100 years, but there are no records of systematic exploration having been conducted. • The USGS undertook regional geochemical sampling work in between 1983 and 1984, with initial stream sediment sampling being followed up with a rock chip sample taken in 1985. Rockchip reported >10,000ppm. The property reportedly produced 30ton of antimony during WWII- this has not been confirmed by the Company. • There are no other reports of other exploration activity to the Company's knowledge. Dollar: • The licences have been subjected to small scale informal mining over several decades, but no systematic exploration has been conducted. • The USGS undertook regional geochemical sampling work in between 1983 and 1984, with initial stream sediment sampling being followed up with a rock chip sample taken in 1985. Rockchip reported >10,000ppm. The property reportedly produced 30ton of antimony during WWII- this has not been confirmed by the Company. There are no other reports of other exploration activity to the

		Company's knowledge.
Geology	• *Deposit type, geological setting and style of mineralization.*	Milton: • The prospect is located in the Union-Grantsville Mining District on the western slope of the Toiyabe Range in Nye County, Nevada. The Toiyabe Range is a horst block composed primarily of uplifted Paleozoic sedimentary rocks, including limestone, shale, and siltstone, which are bordered and locally overlain by Tertiary volcanic rocks. • Mineralisation in the district, particularly for antimony, is structurally controlled and hosted in shear zones and faults. Mineralisation consists of copper, antimony and silver. This geological setting, involving Palaeozoic sediments intruded or overlain by Tertiary volcanics with significant structural preparation, is characteristic of many precious and base metal deposits in the Great Basin Dollar: • The prospect is located in the Jett Mining District on the eastern slope of the Toiyabe Range in Nye County, Nevada. The regional geology map indicates the prospect lies at the contact between Tertiary volcanic rocks and unconsolidated Quaternary sediments. The Toiyabe Range is a horst block composed primarily of uplifted Paleozoic sedimentary rocks, including limestone, shale, and siltstone, which are bordered and locally overlain by Tertiary volcanic rocks. • Mineralization in the district, particularly for antimony, is structurally controlled and hosted in shear zones and faults. A notable occurrence, the Dollar antimony-silver mine, is located at the mouth of Boyd Canyon and features stibnite mineralization along a shear zone at the contact between silicified limestone and shale. This geological setting, involving Paleozoic sediments intruded or overlain by Tertiary volcanics with significant structural preparation, is characteristic of many precious and base metal deposits in the Great Basin

Drill hole Information	• *A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes:*
	  • *easting and northing of the drill hole collar*
	  • *elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar*
	  • *dip and azimuth of the hole*
	  • *down hole length and interception depth*
	  • *hole length.*
	• *If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.*
		• No drilling has been conducted.

Data aggregation methods	• *In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g., cutting of high grades) and cut-off grades are usually Material and should be stated.* • *Where aggregate intercepts incorporate short lengths of high- grade results and longer lengths of low-grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.* • *The assumptions used for any reporting of metal equivalent values should be clearly stated.*	All assay results for principal elements are reported, with no weighted averages or aggregation reported. • No data aggregation has been applied to the results. • No metal equivalent reporting has been made.

Relationship between mineralisation widths and intercept lengths	• *These relationships are particularly important in the reporting of Exploration Results.* • *If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported.* • *If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (eg 'down hole length, true width not known').*	• No relationship between mineralisation widths and intercept lengths can be interpreted due to no drilling having been completed
Diagrams	• *Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported. These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.*	• Diagrams in the report include location maps, regional maps and detailed project area maps. These provide an adequate visual representation of the exploration areas.
Balanced reporting	• *Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.*	• The reports provide a balanced presentation of early-stage geological observations with sample data reported in full. • No selective reporting was used that could misrepresent the overall results. • All available samples and results have been disclosed.

Other substantive exploration data	• *Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.*	• No other activity has been conducted on the Property apart from a reconnaissance trip and grab and channel rockchip samples previously reported on the ASX on January 27th and 28th 2026 and the soil samples reported in this table and release.
Further work	• *The nature and scale of planned further work (eg tests for lateral extensions or depth extensions or large-scale step-out drilling).* • *Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.*	• EV Resources intends to pursue standard early-stage exploration activities in order to define potential drill targets. These includes review of these detailed soil sampling results, and planning for mapping and sampling for planning for the appropriate geophysical method for narrow mineralised systems, which might be conducted prior to a future drilling campaign.
