| <b>Database integrity</b> | <ul style="list-style-type: none"> <li>Measures taken to ensure that data has not been corrupted by, for example, transcription or keying errors, between its initial collection and its use for Mineral Resource estimation purposes.</li> <li>Data validation procedures used.</li> </ul> | <ul style="list-style-type: none"> <li>Data is logged in the field directly into the Geobank mobile device. Lab submission sheets are digitally recorded in the same way. Assay data are received from the laboratories in an electronic format and are imported directly into a standard DataShed system. All data have been validated by the Database Administrator and geological management prior to inclusion in the resource estimate.</li> </ul> |

There is a depletion zone that extends to about 30m below surface in the south of the deposit. The mineralized structure varies from 1m to 23m in width.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Estimation and modelling techniques</b> | <ul style="list-style-type: none"> <li>The nature and appropriateness of the estimation technique(s) applied and key assumptions, including treatment of extreme grade values, domaining, interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</li> <li>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</li> <li>The assumptions made regarding recovery of by-products.</li> <li>Estimation of deleterious elements or other non-grade variables of economic significance (e.g. sulphur for acid mine drainage characterization).</li> <li>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</li> <li>Any assumptions behind modelling of selective mining units.</li> <li>Any assumptions about correlation between variables.</li> <li>Description of how the geological interpretation was used to control the resource estimates.</li> <li>Discussion of basis for using or not using grade cutting or capping.</li> <li>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</li> </ul> | <ul style="list-style-type: none"> <li>EXG has used 3DM wireframes to constrain the mineralised shear zone. All lodes have been interpreted on a sectional basis using the available exploration drilling data on predominantly 20m spaced lines.</li> <li>On the basis of sample size, selectivity assumption (2mE x 5mN x 2.5mRL) and selected estimation methodology, a 1m down hole composite was selected for this estimation. 1m composite intervals falling within the wire framed estimation domains were coded in the database.</li> <li>It was evident that some of the estimation domains contained extreme outlier gold values. The highly positively skewed gold distributions mean that conventional linear estimation methods, such as Ordinary Kriging ("OK") are very likely to produce over-smoothed block grade estimates. For this reason, it was decided to undertake grade estimation using the non-linear Localised Uniform Conditioning ("LUC") method. The following criteria were considered when choosing gold grade top cuts: <ul style="list-style-type: none"> <li>The coherence and stability of the upper tail of the gold grade distribution;</li> <li>Visual inspection of the spatial location of outlier values;</li> <li>The statistics show that in some cases there is a large reduction in mean grade and variability following top cutting. This is due to the elimination of the disproportionate effect of extreme outlier gold grade values. It should be noted that the difficulties posed by these extreme outliers significantly increases the inherent risk in the gold grade estimates.</li> </ul> </li> <li>The LUC estimates were implemented using the Minestis® software package before being transferred into a Micromine™ block model.</li> <li>No consideration has been given to by-products.</li> <li>One check estimate has been undertaken by EXG as a validation step. This is a comparison to an OK resource model completed in 1997 by Goldfields. Results indicate that the LUC model based on exploration data compares to within 2% of contained metal at a 0.5g/t Au cut-off.</li> <li>The estimation panel size used was 8mE x 10mE x 5mRL. An SMU block size of 2mE x 5mN x 2.5mRL was chosen (no rotation) for use in the localisation process. This SMU block size corresponds exactly to the block size for grade control modelling and mining of a similar deposit (Zoroastrian) by EXG. While the data spacing would be considered too wide for such a small block size if conventional linear estimation methods were used, EXG has used the LUC method, which is intended specifically for estimating the grade distribution of smaller blocks.</li> <li>Metallurgical test work has not been done on Duke North mineralisation. No other deleterious elements have been identified.</li> </ul> |

| <b>Environmental factors or assumptions</b> | <ul style="list-style-type: none"> <li>Assumptions made regarding possible waste and process residue disposal options. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider the potential environmental impacts of the mining and processing operation. While at this stage the determination of potential environmental impacts, particularly for a greenfields project, may not always be well advanced, the status of early consideration of these potential environmental impacts should be reported. Where these aspects have not been considered this should be reported with an explanation of the environmental assumptions made.</li> </ul> | <ul style="list-style-type: none"> <li>There are no environmental issues concerning the extraction or disposal of waste or tailing material.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Bulk density</b>                         | <ul style="list-style-type: none"> <li>Whether assumed or determined. If assumed, the basis for the assumptions. If determined, the method used, whether wet or dry, the frequency of the measurements, the nature, size and representativeness of the samples.</li> <li>The bulk density for bulk material must have been measured by methods that adequately account for void spaces (vugs, porosity, etc), moisture and differences between rock and alteration zones within the deposit.</li> <li>Discuss assumptions for bulk density estimates used in the evaluation process of the different materials.</li> </ul>                                                                                                     | <ul style="list-style-type: none"> <li>Bulk density determinations specific to Duke North ore and waste have not been undertaken. Results from a similar deposit in the region (Zoroastrian) have been utilized for this MRE. The following describe the sources of data used for the Zoroastrian deposit which is also dolerite hosted:</li> <li>There are three sources of experimental bulk density data.</li> <li>The first are the results of systematically collected DD core measurements and the second were downhole caliper SG readings every 0.1m for selected holes. The third source was bulk in-pit density determinations gathered by the mining staff. The DD core results provide a source of competent rock bulk density data however the data lacks any representative data for less competent oxide and transitional weathered rock. The in-pit data represents an attempt to measure the densities of the less competent material.</li> <li>A total of 103 determinations have been made from 13 EXD DD holes. Determinations were made using two methods – for 5 holes the densities were determined using a down hole probe, the Auslog A659 Caliper Tool, the balance were selected core sent to the Genalysis Laboratory in Kalgoorlie where specific gravity was determined by gravimetric technique. The majority of these data were taken on fresh dolerite core, with a small number of oxidised and transitional dolerite core results. The average depth of these determinations is 104m downhole.</li> <li>A total of 190 in-pit determinations have been made between the 430m, and 400m pit floor RLs, at surveyed locations within 29 high and low grade ore mark-out blocks. The RLs of these determinations places them within the oxide and transitional weathering profile.</li> <li>On balance EXG believe that there are sufficient data to allow the assignment of average values to the MRE block model but not enough to allow a spatially representative estimation of bulk density. EXG have used assumed bulk density values for ore and waste based on the interpreted weathering surfaces. The bulk of the Duke North MRE is within dolerite and the densities applied are appropriate. For the minor portions of the MRE within sediment and ultramafic there are likely to some variations in bulk density.</li> </ul> |
| <b>Classification</b>                       | <ul style="list-style-type: none"> <li>The basis for the classification of the Mineral Resources into varying confidence categories.</li> <li>Whether appropriate account has been taken of all relevant factors (i.e. relative confidence in tonnage/grade estimations, reliability of input data,</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                 | <ul style="list-style-type: none"> <li>The geological model and continuity of the mineralisation is currently well understood due to the relatively close spaced RC drilling.</li> <li>The MRE is classified into indicated and inferred to reflect the confidence in the estimate of different areas of the MRE. | <b>Discussion of relative accuracy/confidence</b> | <ul style="list-style-type: none"> <li>Where appropriate a statement of the relative accuracy and confidence level in the Mineral Resource estimate using an approach or procedure deemed appropriate by the Competent Person. For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the resource within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors that could affect the relative accuracy and confidence of the estimate.</li> <li>The statement should specify whether it relates to global or local estimates, and, if local, state the relevant tonnages, which should be relevant to technical and economic evaluation. Documentation should include assumptions made and the procedures used.</li> <li>These statements of relative accuracy and confidence of the estimate should be compared with production data, where available.</li> </ul> | <ul style="list-style-type: none"> <li>The relative accuracy of the Mineral Resource estimate is reflected in the reporting of the Mineral Resource in accordance with the guidelines of the 2012 JORC Code.</li> <li>Grade and geological continuity can be estimated to a degree of accuracy high enough to allow for a proportion of the resource to be classified as Indicated or Inferred where appropriate.</li> <li>The LUC block model estimate is a local resource estimate which has block sizes chosen at the expected "SMU" selection size. Globally the accuracy of the estimate has not been quantified by simulation or similar methods. However the overall tonnage and grade compares favorably with a previous estimate, the total metal being within 2%.</li> </ul> |

## JORC Table 1 Checklist of Assessment and Reporting Criteria – EL DORADO

### Section 1 Sampling techniques and data – El Dorado

| Criteria                     | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Commentary                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sampling techniques</b>   | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>The mineralisation was primarily sampled by Reverse Circulation (RC) drilling on nominal 40m x 20m (N x E) grid spacing. The holes were generally drilled towards magnetic 235 degrees at varying angles to optimally intersect the mineralized zones.</li> <li>Complete details are unavailable for historic drilling.</li> <li>RC chip samples were collected and passed through a cone splitter in 1m intervals.</li> <li>Limited numbers of field duplicates and screen fire assays have been undertaken to support sample representivity.</li> <li>All RC drilling was sampled on one metre down hole intervals. The recovered samples were passed through a cone splitter and a nominal 2.5kg – 3.5kg sample was taken to a Kalgoorlie contract laboratory. Samples were oven dried, reduced by riffle splitting to 3kg as required and pulverized in a single stage process to 85% passing 75µm. The sample was then prepared by standard fire assay techniques with a 40g charge. Approximately 200g of pulp material was returned to for storage and potential additional assay at a later date.</li> </ul> |
| <b>Drilling techniques</b>   | <ul style="list-style-type: none"> <li>Drill type (e.g. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g. core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <ul style="list-style-type: none"> <li>RAB drilling makes up about 5% of the historic drilling and RC the other 95%. There are several campaigns of historic drilling between 1984 and 1995. These holes are sometimes without documentation of the rig type and capability, core size, sample selection and handling.</li> <li>For (post 2009) drilling, the RC drilling system employed the use of a face sampling hammer and a nominal 146mm diameter drill bit</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Drill sample recovery</b> | <ul style="list-style-type: none"> <li>Method of recording and assessing core and chip sample recoveries and results assessed</li> <li>Measures taken to maximise sample recovery and ensure representative nature of the samples</li> <li>Whether a relationship exists between sample recovery and grade and</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <ul style="list-style-type: none"> <li>All RC 1m samples are logged for drilling recovery by a visual estimate and this information was recorded and stored in the drilling database. At least every 10th metre was collected in a plastic bag and these are weighed when they are utilized for the collection of field duplicate samples. All samples received by the laboratory are weighed with the data collected and stored in the database.</li> <li>RC samples were visually logged for moisture content, sample recovery and contamination. | <b>Sub-sampling techniques and sample preparation</b> | <ul style="list-style-type: none"> <li><i>If core, whether cut or sawn and whether quarter, half or all core taken.</i></li> <li><i>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</i></li> <li><i>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</i></li> <li><i>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</i></li> <li><i>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.</i></li> <li><i>Whether sample sizes are appropriate to the grain size of the material being sampled.</i></li> </ul> | <ul style="list-style-type: none"> <li>All RC samples were put through a cone splitter and the sub sample was collected in a unique pre-numbered calico sample bag. The moisture content and volume recovered of each sample was recorded in the database.</li> <li>The RC samples were sorted, oven dried, the entire sample was pulverized in a one stage process to 85% passing 75µm. The bulk pulverized sample was then bagged and approximately 200g extracted by spatula to a numbered paper bag that was used for the 50g fire assay charge.</li> <li>RC and DC samples submitted to the laboratory were sorted and reconciled against the submission documents. BDC inserted blanks and standards with blanks submitted in sample number sequence at 1 in 50 and standards submitted in sample number sequence at 1 in 20. The laboratory used their own internal standards of 2 duplicates, 2 replicates, 2 standards, and 1 blank per 50 fire assays. The laboratory also uses barren flushes on the pulveriser.</li> <li>In the field every 10th metre from cone splitter was bagged and placed in order on the ground with other samples. This sample was then used for collection of field duplicates via riffle splitting. RC field duplicate samples were collected after results were received from the original sample assay. Generally, field duplicates were only collected where the original assay result was equal to or greater than 0.1g/t Au. The field duplicates were submitted to the laboratory for the standard assay process. The laboratory was blind to the original sample number.</li> <li>The sample sizes were considered to be appropriate for the type, style, thickness, grain size and consistency of mineralisation located at this project. The sample size was also appropriate for the sampling methodology employed and the gold grade ranges returned.</li> </ul> |
| <b>Quality of assay data and laboratory tests</b>     | <ul style="list-style-type: none"> <li><i>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</i></li> <li><i>For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</i></li> <li><i>Nature of quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.</i></li> </ul>                                                                                              | <ul style="list-style-type: none"> <li>BDC routinely used local Kalgoorlie Certified Laboratories for all sample preparation and analysis. The most commonly used laboratories have been Intertek Genalysis and Bureau Veritas Australia. No complete details of the sample preparation, analysis or security were available for either the historic RAB, AC, DD or RC drilling results in the database.</li> <li>The assay method was designed to measure total gold in the sample. The laboratory procedures were appropriate for the testing of gold at this project given its mineralisation style. The technique involves using a 40g or 50g sample charge with a lead flux which was decomposed in a furnace with the prill being totally digested by 2 acids (HCl and HNO3) before measurement of the gold content by an AA machine.</li> <li>The QC procedures were industry best practice. The laboratories were accredited and use their own certified reference materials.</li> <li>BDC submitted blanks at the rate of 1 in 50 samples and certified reference material standards at the rate of 1 in 20 samples in the normal run of sample submission numbers. As part of normal procedures BDC examines all standards and blanks to ensure that they were within tolerances. Additionally, sample size, grind size and field duplicates were examined to ensure no bias to gold grade exists.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Estimation and modelling techniques</b> | <ul style="list-style-type: none"> <li>The nature and appropriateness of the estimation technique(s) applied and key assumptions, including treatment of extreme grade values, domaining, interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</li> <li>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</li> <li>The assumptions made regarding recovery of by-products.</li> <li>Estimation of deleterious elements or other non-grade variables of economic significance (e.g. sulphur for acid mine drainage characterization).</li> <li>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</li> <li>Any assumptions behind modelling of selective mining units.</li> <li>Any assumptions about correlation between variables.</li> <li>Description of how the geological interpretation was used to control the resource estimates.</li> <li>Discussion of basis for using or not using grade cutting or capping.</li> <li>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</li> </ul> | <ul style="list-style-type: none"> <li>BDC used 3DM wireframes interpreted on a sectional basis to constrain the mineralised zones, based on RC drilling at spacings down to 15m N x 15m E-W.</li> <li>1m compositing was considered appropriate for the estimation given the sometimes narrow nature of the steep lodes. 1m composite intervals falling within the wire framed estimation domains were coded in the database.</li> <li>Influences of extreme sample distribution outliers were reduced by top-cutting on a domain basis. Top-cuts were decided by using a combination of methods including grade histograms, log probability plots and statistical tools plus visual inspection of the spatial location of outlier values. Based on this statistical analysis of the data population some top cuts were applied, including domains D1 (25 ppm), D2 (20 ppm) and D3 (15 ppm).</li> <li>Grade estimation using Ordinary Kriging (OK) was completed using Geovia Surpac™ software for Au only.</li> <li>Directional variograms were modelled by domain using traditional variograms. Nugget values are moderate to high (around 50%) and structure ranges up to 70m. The variograms were poorly formed and with D1 containing the most samples, its modelled variography was applied to the remainder of the domains.</li> <li>Block model was constructed with parent blocks of 2m (E) by 5m (N) by 10m (RL) and sub-blocked down to 0.5m (E) by 1.25m (N) by 2.5m (RL). All estimation was completed to the parent cell size. Discretisation was set to 5 by 5 by 2 for all domains.</li> <li>Three estimation passes were used with the first pass using a limit of 30m, the second pass 60m and the third pass searching a large distance to fill the blocks within the wire framed zones. Each pass used a maximum of 12 samples, a minimum of 6 samples and maximum per hole of 3 samples.</li> <li>Search ellipse sizes were based primarily on a combination of the variography and the trends of the wire framed mineralized zones. Hard boundaries were applied between all estimation domains.</li> <li>Validation of the block model included a volumetric comparison of the resource wireframes to the block model volumes. Validation of the grade estimate included comparison of block model grades to the declustered input composite grades plus swath plot comparison by easting, northing and elevation. Visual comparisons of input composite grades vs. block model grades were also completed.</li> <li>No consideration has been made to by-products.</li> </ul> |

| <b>Sampling techniques</b>   | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>The mineralisation was primarily sampled by Reverse Circulation (RC) and Diamond Core (DC) drilling on nominal 40m x 20m (N x E) grid spacing. The holes were generally drilled towards grid east at varying angles to optimally intersect the mineralized zones.</li> <li>Complete details are un-available for historic drilling.</li> <li>Generally, BDC RC recovered chip samples were collected and passed through a cone splitter.</li> <li>Limited numbers of field duplicates have been undertaken to support sample representivity.</li> <li>All BDC RC drilling was sampled on one metre down hole intervals. The recovered samples were passed through a cone splitter and a nominal 2.5kg – 3.5kg sample was taken to a Kalgoorlie contract laboratory. Samples were oven dried, reduced by riffle splitting to 3kg as required and pulverized in a single stage process to 85% passing 75µm. The sample is then prepared by standard fire assay techniques with a 40g charge. Approximately 200g of pulp material is returned to BDC for storage and potential assay at a later date. The BDC DC samples are collected at nominated intervals by BDC staff from core that has been cut in half. Samples were oven dried, crushed to a nominal 10mm by a jaw crusher, reduced by riffle splitting to 3kg as required and pulverized in a single stage process to 85% passing 75µm. The sample is then prepared by standard fire assay techniques with a 40g charge. Approximately 200g of pulp material is returned to BDC for storage and potential assay at a later date.</li> </ul>                                                             |
| <b>Drilling techniques</b>   | <ul style="list-style-type: none"> <li>Drill type (e.g. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g. core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is orientated and if so, by what method, etc).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <ul style="list-style-type: none"> <li>There is a significant historical data set of drill and sample data for Talbot North. It is comprised of RAB 12%, trench sampling from open pit grade control 35% and RC/DC 53%.</li> <li>For (post 2009) BDC drilling, the RC drilling system employed the use of a face sampling hammer and a nominal 146mm diameter drill bit. The DC drilling is NQ2 size core (nominal 50.6mm core diameter).</li> <li>All BDC drill core is orientated by the drilling contractor, usually every 3m run.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Drill sample recovery</b> | <ul style="list-style-type: none"> <li>Method of recording and assessing core and chip sample recoveries and results assessed</li> <li>Measures taken to maximise sample recovery and ensure representative nature of the samples</li> <li>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <ul style="list-style-type: none"> <li>All BDC RC 1m samples are logged for drilling recovery by a visual estimate and this information is recorded and stored in the drilling database. At least every 10th metre is collected in a plastic bag and these are weighed when they are utilized for the collection of field duplicate samples. All samples received by the laboratory are weighed with the data collected and stored in the database.</li> <li>The BDC DC samples are orientated, length measured and compared to core blocks placed in the tray by the drillers, any core loss or other variance from that expected from the core blocks is logged and recorded in the database. Sample loss or gain is reviewed on an ongoing basis and feedback given to the drillers to enable the best representative sample to always be obtained.</li> <li>BDC RC 1m samples are visually logged for moisture content, sample recovery and contamination. This information is stored in the database. The RC drill system utilizes a face sampling hammer which is industry best practice and the contractor aims to maximize recovery at all times. RC holes are drilled dry whenever practicable to maximize recovery of sample.</li> <li>The DC drillers use a core barrel and wire line unit to recover the core, they aim to recover all core at all times and adjust their drilling methods and rates to minimise core loss, i.e. different techniques for broken ground to ensure as little core as possible is washed away with drill cuttings.</li> <li>Study of sample recovery vs gold grade does not show any bias towards differing sample recoveries or gold grade. The</li> </ul> |

| Criteria                                              | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Commentary                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Core (or costean, channel, etc) photography.</li> <li>The total length and percentage of the relevant intersections logged.</li> </ul>                                                                                                                                                                                                                                                                                             | <p>drilling contractor uses standard industry drilling techniques to ensure minimal loss of any size fraction.</p> <ul style="list-style-type: none"> <li>All BDC RC samples are geologically logged directly into hand-held Geobank devices.</li> <li>All BDC DC is logged for core loss, marked into metre intervals, orientated, structurally logged, geotechnically logged and logged with a hand lens with the following parameters recorded where observed: weathering, regolith, rock type, alteration, mineralisation, shearing/foliation and any other features that are present</li> <li>All BDC DC is photographed both wet and dry after logging but before cutting.</li> <li>The entire lengths of BDC RC holes are logged on a 1m interval basis, i.e. 100% of the drilling is logged, and where no sample is returned due to voids (or potentially lost sample) it is logged and recorded as such. Drill core is logged over its entire length (ie 100%) and any core loss or voids intersected are recorded.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Sub-sampling techniques and sample preparation</b> | <ul style="list-style-type: none"> <li>If core, whether cut or sawn and whether quarter, half or all core taken.</li> <li>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</li> <li>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</li> <li>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</li> <li>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.</li> <li>Whether sample sizes are appropriate to the grain size of the material being sampled.</li> </ul> | <ul style="list-style-type: none"> <li>All BDC RC samples are put through a cone splitter and the sample is bagged on site by the drilling contractor into pre-numbered calico bags.</li> <li>All BDC RC samples are put through a cone splitter and the sample is collected in a unique pre-numbered calico sample bag. The moisture content of each sample is recorded in the database.</li> <li>The BDC RC samples are sorted, oven dried, the entire sample is pulverized in a one stage process to 85% passing 75µm. The bulk pulverized sample is then bagged and approximately 200g extracted by spatula to a numbered paper bag that is used for the 40g fire assay charge.</li> <li>The BDC DC samples are oven dried, jaw crushed to nominal &lt;10mm, 3.5kg is obtained by riffle splitting and the remainder of the coarse reject is bagged while the 3.5kg is pulverized in a one stage process to 85% passing 75µm. The bulk pulverized sample is then bagged and approximately 200g extracted by spatula to a numbered paper bag that is used for a 40g fire assay charge.</li> <li>BDC uses ½ core sawn by an automated core saw as standard procedure. The retained ½ of the core is the part of the core that contains the drill hole orientation line and depth intervals. The retained ½ is stored in systematic way in the Company's on site core yard.</li> <li>BDC RC and DC samples submitted to the laboratory are sorted and reconciled against the submission documents. BDC inserts blanks and standards with blanks submitted in sample number sequence at 1 in 50 and standards submitted in sample number sequence at 1 in 20. The laboratory uses their own internal standards of 2 duplicates, 2 replicates, 2 standards, and 1 blank per 50 fire assays. The laboratory also uses barren flushes on the pulveriser.</li> <li>In the field every 10th metre from the bulk sample port on the cone splitter is bagged and placed in order on the ground with other samples. This sample is then used for collection of field duplicates via riffle splitting. RC field duplicate samples are collected after results are received from the original sample assay. Generally, field duplicates are only collected where the original assay result is equal to or greater than 0.1g/t Au. The field duplicates are submitted to the laboratory for the standard assay process. The laboratory is blind to the original sample number.</li> <li>For DC, historically no core duplicates (i.e. half core) have been collected or submitted. For the current program the lab was requested to take a sample from the crush reject as a proxy for the field duplicate.</li> <li>The sample sizes are considered to be appropriate for the type, style, thickness and consistency of mineralisation located at this project. The sample size is also appropriate for the sampling methodology employed and the gold grade ranges returned.</li> </ul> |
| <b>Quality of assay data and laboratory tests</b>     | <ul style="list-style-type: none"> <li>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</li> <li>For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</li> <li>Nature of quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.</li> </ul>                                                                         | <ul style="list-style-type: none"> <li>BDC has routinely used local Kalgoorlie Certified Laboratories for all sample preparation and analysis. The most commonly used laboratories have been Intertek Genalysis and Bureau Veritas Australia. No complete details of the sample preparation, analysis or security are available for either the historic AC, DD or RC drilling results in the database.</li> <li>The assay method is designed to measure total gold in the sample. The laboratory procedures are appropriate for the testing of gold at this project given its mineralisation style. The technique involves using a 40g sample charge with a lead flux which is decomposed in a furnace with the prill being totally digested by 2 acids (HCl and HNO3) before measurement of the gold content by an AA machine.</li> <li>The QC procedures are industry best practice. The laboratories are accredited and use their own certified reference materials.</li> <li>BDC submits blanks at the rate of 1 in 50 samples and certified reference material standards at the rate of 1 in 20 samples in the normal run of sample submission numbers. As part of normal procedures BDC examines all standards and blanks to ensure that they are within tolerances. Additionally, sample size, grind size and field duplicates are examined to ensure no bias to gold grade exists.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

It has three lithologies which strike NW and dip 65o to 80o to the south west. From west to east these are shale, basalt and ultramafic. The western sediments are part of the Black Flag Beds. The basalt varies in width from about 90m in the south to 40m in the north. The basalt is separated by two shale units of varying width between 30cm to 10m. Mineralisation lies almost entirely within the basalt, being both lithologically and structurally controlled. Mineralisation along the western contact is associated with a contact parallel quartz vein in the footwall. A pervasive chlorite-carbonate alteration with arsenopyrite is associated with the gold mineralisation. NE striking structures appear to dextrally offset the mineralisation in places and may increase gold grades locally.</li> </ul> |

| <b>Sampling techniques</b>   | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>The mineralisation was primarily sampled by Reverse Circulation (RC) and Diamond Core (DC) drilling on nominal 40m x 20m (N x E) grid spacing. The holes were generally drilled towards grid east at varying angles to optimally intersect the mineralized zones.</li> <li>Complete details are unavailable for historic drilling.</li> <li>Generally, BDC RC recovered chip samples were collected and passed through a cone splitter.</li> <li>Limited numbers of field duplicates have been undertaken to support sample representivity.</li> <li>All BDC RC drilling was sampled on one metre down hole intervals. The recovered samples were passed through a cone splitter and a nominal 2.5kg – 3.5kg sample was taken to a Kalgoorlie contract laboratory. Samples were oven dried, reduced by riffle splitting to 3kg as required and pulverized in a single stage process to 85% passing 75µm. The sample is then prepared by standard fire assay techniques with a 40g charge. Approximately 200g of pulp material is returned to BDC for storage and potential assay at a later date. The BDC DC samples are collected at nominated intervals by BDC staff from core that has been cut in half. Samples were oven dried, crushed to a nominal 10mm by a jaw crusher, reduced by riffle splitting to 3kg as required and pulverized in a single stage process to 85% passing 75µm. The sample is then prepared by standard fire assay techniques with a 40g charge. Approximately 200g of pulp material is returned to BDC for storage and potential assay at a later date.</li> </ul> |

Drill core is logged over its entire length (ie 100%) and any core loss or voids intersected are recorded.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Sub-sampling techniques and sample preparation</b> | <ul style="list-style-type: none"> <li>If core, whether cut or sawn and whether quarter, half or all core taken.</li> <li>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</li> <li>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</li> <li>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</li> <li>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.</li> <li>Whether sample sizes are appropriate to the grain size of the material being sampled.</li> </ul> | <ul style="list-style-type: none"> <li>All BDC RC samples are put through a cone splitter and the sample is bagged on site by the drilling contractor into pre-numbered calico bags.</li> <li>All BDC RC samples are put through a cone splitter and the sample is collected in a unique pre-numbered calico sample bag. The moisture content of each sample is recorded in the database.</li> <li>The BDC RC samples are sorted, oven dried, the entire sample is pulverized in a one stage process to 85% passing 75µm. The bulk pulverized sample is then bagged and approximately 200g extracted by spatula to a numbered paper bag that is used for the 40g fire assay charge.</li> <li>The BDC DC samples are oven dried, jaw crushed to nominal &lt;10mm, 3.5kg is obtained by riffle splitting and the remainder of the coarse reject is bagged while the 3.5kg is pulverized in a one stage process to 85% passing 75µm. The bulk pulverized sample is then bagged and approximately 200g extracted by spatula to a numbered paper bag that is used for a 40g fire assay charge.</li> <li>BDC uses ½ core sawn by an automated core saw as standard procedure. The retained ½ of the core is the part of the core that contains the drill hole orientation line and depth intervals. The retained ½ is stored in systematic way in the Company's on-site core yard.</li> <li>BDC RC and DC samples submitted to the laboratory are sorted and reconciled against the submission documents. BDC inserts blanks and standards with blanks submitted in sample number sequence at 1 in 50 and standards submitted in sample number sequence at 1 in 20. The laboratory uses their own internal standards of 2 duplicates, 2 replicates, 2 standards, and 1 blank per 50 fire assays. The laboratory also uses barren flushes on the pulveriser.</li> <li>In the field every 10<sup>th</sup> metre from the bulk sample port on the cone splitter is bagged and placed in order on the ground with other samples. This sample is then used for collection of field duplicates via riffle splitting. RC field duplicate samples are collected after results are received from the original sample assay. Generally, field duplicates are only collected where the original assay result is equal to or greater than 0.1g/t Au. The field duplicates are submitted to the laboratory for the standard assay process. The laboratory is blind to the original sample number.</li> <li>For DC, historically no core duplicates (i.e. half core) have been collected or submitted. For the current program the lab was requested to take a sample from the crush reject as a proxy for the field duplicate.</li> <li>The sample sizes are considered to be appropriate for the type, style, thickness and consistency of mineralisation located at this project. The sample size is also appropriate for the sampling methodology employed and the gold grade ranges returned.</li> </ul> |

|                                                                | <p>parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</p> <ul style="list-style-type: none"> <li>Nature of quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.</li> </ul> | <ul style="list-style-type: none"> <li>The assay method is designed to measure total gold in the sample. The laboratory procedures are appropriate for the testing of gold at this project given its mineralisation style. The technique involves using a 40g sample charge with a lead flux which is decomposed in a furnace with the prill being totally digested by 2 acids (HCl and HNO<sub>3</sub>) before measurement of the gold content by an AA machine.</li> <li>The QC procedures are industry best practice. The laboratories are accredited and use their own certified reference materials.</li> <li>BDC submits blanks at the rate of 1 in 50 samples and certified reference material standards at the rate of 1 in 20 samples in the normal run of sample submission numbers. As part of normal procedures BDC examines all standards and blanks to ensure that they are within tolerances. Additionally, sample size, grind size and field duplicates are examined to ensure no bias to gold grade exists.</li> </ul>                                                                                     |
| <b>Verification of sampling and assaying</b>                   | <ul style="list-style-type: none"> <li>The verification of significant intersections by either independent or alternative company personnel.</li> <li>The use of twinned holes.</li> <li>Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.</li> <li>Discuss any adjustment to assay data.</li> </ul>                                                     | <ul style="list-style-type: none"> <li>BDC's Exploration Manager and Senior Resource Geologist have inspected RC chips and drill core in the field to verify the correlation of mineralized zones between assay results and lithology/alteration/mineralisation.</li> <li>A number of RC holes have also been drilled that confirmed results obtained from historical drillholes. No holes have been directly twinned; there are however holes within 15m of each other.</li> <li>Primary data is sent digitally every 2-3 days from the field to BDC's Database Administrator (DBA). The DBA imports the data into the commercially available and industry accepted DataShed database software. Assay results are merged when received electronically from the laboratory. The responsible geologist reviews the data in the database to ensure that it is correct and has merged properly and that all data has been received and entered. Any variations that are required are recorded permanently in the database.</li> <li>No adjustments or calibrations were made to any assay data used in this report.</li> </ul> |
| <b>Location of data points</b>                                 | <ul style="list-style-type: none"> <li>Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation</li> <li>Specification of the grid system used</li> <li>Quality and adequacy of topographic control.</li> </ul>                                                                                                 | <ul style="list-style-type: none"> <li>All drill holes have their collar location recorded from a differential RTK GPS unit by consultant surveyors. Downhole surveys are completed every 30m downhole during drilling and 5m intervals after end of hole. Incomplete down hole surveying information is available for the historic RC or DD drilling.</li> <li>BDC routinely contracted down hole surveys during the programmes of exploration drilling for each drill hole completed using either digital electronic multi-shot tool or north seeking gyro, both of which are maintained by Contractors to manufacturer specifications. The current drill program was downhole surveyed by the drill contractor using north seeking gyro.</li> <li>All drill holes and resource estimation use the MGA94, Zone 51 grid system.</li> <li>The topographic data used was obtained from a LIDAR survey flown in 2012 and it is adequate for the reporting of Exploration Results and subsequent Mineral Resource Estimates.</li> </ul>                                                                                        |

This mineralisation is associated with intense shearing and quartz, sericite, carbonate, sulphide alteration. The development of possible stockworks at intersections of structures is also interpreted. Whilst structures and primary gold mineralisation can be traced to the surface depletion has occurred in the top 20-30m and again through the transitional zone. Sub-horizontal supergene enrichment blankets occur throughout the regolith. Historical workings and shafts exist within the area. Detailed mapping and sampling of these workings and structural measurements forms the basis of the geological interpretation.</li></ul> |             |        |           |             |         |                       |       |            |

Nugget values are high (around 50%) and structure ranges up to 70m. The variograms were poorly formed and with D1 containing the most samples, its modelled variography was applied to the remainder of the domains.</li> <li>Block model was constructed with parent blocks of 2m (E) by 10m (N) by 10m (RL) and sub-blocked down to 0.5m (E) by 2.5m (N) by 2.5m (RL). All estimation was completed to the parent cell size. Discretisation was set to 5 by 5 by 2 for all domains.</li> <li>Three estimation passes were used with the first pass using a limit of 30m, the second pass 60m and the third pass searching a large distance to fill the blocks within the wire framed zones. Each pass used a maximum of 12 samples, a minimum of 6 samples and maximum per hole of 3 samples.</li> <li>Search ellipse sizes were based primarily on a combination of the variography and the trends of the wire framed mineralized zones. Hard boundaries were applied between all estimation domains.</li> <li>Validation of the block model included a volumetric comparison of the resource wireframes to the block model volumes. Validation of the grade estimate included comparison of block model grades to the declustered input composite grades plus swath plot comparison by easting, northing and elevation. Visual comparisons of input composite grades vs. block model grades were also completed.</li> <li>No consideration has been made to by-products.</li> </ul> |

| <b>Sampling techniques</b> | <ul style="list-style-type: none"> <li>Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual</li> </ul> | <ul style="list-style-type: none"> <li>Drill holes used in the estimate include 5 diamond holes ("DD") and 196 reverse circulation ("RC") holes. In addition, large number of regional Rotary Air Blast ("RAB") and air-core ("AC") holes have been completed;</li> <li>The mineralisation was primarily sampled by Reverse Circulation (RC) majority of RC and DD drilling on nominal 40m x 20m (N x E) grid spacing. The was completed between 1985 and 2014 by various companies. SPM completed 58 holes in 2014;</li> <li>In the deposit area, holes were generally drilled towards magnetic 090 degrees</li> <li>at varying angles to optimally intersect the mineralised zones.;</li> <li>Complete details are un-available for historic drilling.</li> <li>BDC RC chip samples were collected and passed through a cone splitter in 1m or 2m intervals. from a rig mounted cyclone and riffle splitter;</li> <li>Limited numbers of field duplicates and screen fire assays have been undertaken to support sample representivity.</li> <li>All BDC RC drilling was sampled on one metre down hole intervals. The recovered samples were passed through a cone splitter and a nominal 2.5kg – 3.5kg sample was taken to a Kalgoorlie contract laboratory. Samples were oven</li> </ul> |

| <b>Environmental factors or assumptions</b>       | <ul style="list-style-type: none"> <li>Assumptions made regarding possible waste and process residue disposal options. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider the potential environmental impacts of the mining and processing operation. While at this stage the determination of potential environmental impacts, particularly for a greenfields project, may not always be well advanced, the status of early consideration of these potential environmental impacts should be reported. Where these aspects have not been considered this should be reported with an explanation of the environmental assumptions made.</li> </ul>                                                                                                                                                                                                                                                            | <ul style="list-style-type: none"> <li>The area is not known to be environmentally sensitive and there is no reason to think that approvals for development including the dumping of waste would not be approved.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Sampling techniques</b>                            | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>The mineralisation was primarily sampled by Reverse Circulation (RC) drilling on nominal 40m x 20m (N x E) grid spacing. The holes were generally drilled towards magnetic 090 degrees at varying angles to optimally intersect the mineralized zones.</li> <li>Complete details are unavailable for historic drilling.</li> <li>BDC RC chip samples were collected and passed through a cone splitter in 1m intervals.</li> <li>Limited numbers of field duplicates and screen fire assays have been undertaken to support sample representivity.</li> <li>All BDC RC drilling was sampled on one metre down hole intervals. The recovered samples were passed through a cone splitter and a nominal 2.5kg – 3.5kg sample was taken to a Kalgoorlie contract laboratory. Samples were oven dried, reduced by riffle splitting to 3kg as required and pulverized in a single stage process to 85% passing 75µm. The sample is then prepared by standard fire assay techniques with a 40g charge. Approximately 200g of pulp material is returned to BDC for storage and potential additional assay at a later date</li> </ul>                                                                                                                                 |

East of the shale is a heavily weathered dolerite body which is narrow to the south and widens considerably to the north. Moderate milky quartz veining is present within the lithology. The eastern contact between dolerite and ultramafics is intensely sheared. Most of the mineralisation is within the Zoroastrian Dolerite. The mineralisation is similar to that seen at Zoroastrian with a north-south trending shear zone with minor arsenopyrite.</li></ul> |             |        |           |             |         |               |       |            |         |               |      |            |

|                                             | <ul style="list-style-type: none"> <li>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</li> <li>The assumptions made regarding recovery of by-products.</li> <li>Estimation of deleterious elements or other non-grade variables of economic significance (e.g. sulphur for acid mine drainage characterization).</li> <li>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</li> <li>Any assumptions behind modelling of selective mining units.</li> <li>Any assumptions about correlation between variables.</li> <li>Description of how the geological interpretation was used to control the resource estimates.</li> <li>Discussion of basis for using or not using grade cutting or capping.</li> <li>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</li> </ul> | <p>decided by using a combination of methods including grade histograms, log probability plots and statistical tools plus visual inspection of the spatial location of outlier values. Based on this statistical analysis of the data population some top cuts were applied, including domains D1 and D8 (20 ppm) and D5, 6 10 and 12 (10 ppm).</p> <ul style="list-style-type: none"> <li>Grade estimation using Ordinary Kriging (OK) was completed using Geovia Surpac™ software for Au only.</li> <li>Directional variograms were modelled by domain using traditional variograms. Nugget values are moderate to high (around 40%) and structure ranges up to 70m. The variograms were poorly formed and with D1 containing the most samples, its modelled variography was applied to the remainder of the domains.</li> <li>Block model was constructed with parent blocks of 2m (E) by 10m (N) by 10m (RL) and sub-blocked down to 0.5m (E) by 2.5m (N) by 2.5m (RL). All estimation was completed to the parent cell size. Discretisation was set to 5 by 5 by 2 for all domains.</li> <li>Three estimation passes were used with the first pass using a limit of 30m, the second pass 60m and the third pass searching a large distance to fill the blocks within the wire framed zones. Each pass used a maximum of 12 samples, a minimum of 6 samples and maximum per hole of 3 samples.</li> <li>Search ellipse sizes were based primarily on a combination of the variography and the trends of the wire framed mineralized zones. Hard boundaries were applied between all estimation domains.</li> <li>Validation of the block model included a volumetric comparison of the resource wireframes to the block model volumes. Validation of the grade estimate included comparison of block model grades to the declustered input composite grades plus swath plot comparison by easting, northing and elevation. Visual comparisons of input composite grades vs. block model grades were also completed.</li> <li>No consideration has been made to by-products.</li> </ul> |

| <b>Sampling techniques</b> | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual</li> </ul> | <ul style="list-style-type: none"> <li>The mineralisation was sampled by Reverse Circulation (RC) and Diamond Core (DC) drilling on variable drilling spacing. The sampling, collection and sub-setting methods are at or above Industry Standard Practise (explained further below). The holes were drilled to optimally intersect the targeted mineralized zones. The majority of holes were drilled with a dip of -60° with azimuths of either 90° or 270° magnetic. It is noted that drilling has failed to adequately test for potential cross cutting structures that may or may not influence gold distribution.</li> <li>The drill hole locations are considered sufficient to provide for the spatial spread of samples across multiple mineralized zones and different rock types. All EXG RC samples were collected and passed through a cone splitter. Diamond core was HQ or NQ2 in size and drilled with a dip of -60° with azimuths of either 90° or 270° magnetic. Holes positions were surveyed by a qualified surveyor and holes were down hole surveyed by contractors. Instruments used were No records exist for how the diamond core drilled was collected, handled or sampled</li> <li>All RC drilling by EXG was collected on one metre down hole intervals. The recovered samples were passed through a cone and/or a riffle splitter to collect a nominal 2.5kg – 3.5kg sample before having a 50g fire assay. Historic sampling had every 2nd metre submitted for assay and samples either side submitted if anomalous results</li> </ul> |

At least every 10th metre is collected in a plastic bag and these are weighed when they are utilised for the collection of field duplicate samples. The weight of the sample in the plastic bag is recorded and the total sample recovery can be calculated. All samples received by the laboratory are weighed with the data collected and stored in the database. The DC samples are orientated; length measured and compared to core blocks placed in the tray by the drillers, any core loss or other variance from that expected from the core blocks is logged and recorded in the database. Sample loss or gain is reviewed on an ongoing basis and feedback given to the drillers to enable the best representative sample to always be obtained. Limited historical information is available on sampling recoveries and QAQC methods within the historical reports reviewed. However, given the companies involved (Goldfields, Placer Dome), and that the drilling was conducted between 1995 and 2006 it is considered that the work undertaken is of sufficient quality to estimate JORC resources.</li> <li>RC samples are visually logged for moisture content, sample recovery and contamination. This information is stored in the database. The RC drill system utilises industry standard face sampling hammers with a competent drilling contractor who used their best endeavours to maximise sample recovery at all times. The DC drillers use a core barrel and wireline unit to recover the core, they aim to recover all core at all times and adjust their drilling methods and rates to minimise core loss, i.e. different techniques for broken ground to ensure as little core as possible is washed away with drill cuttings.</li> <li>For EXG drilling, no bias is observed when reviewing sample size vs gold grades. No historical information is available for review.</li> </ul> |

Core (or costean, channel, etc) photography.</li> <li>The total length and percentage of the relevant intersections logged</li> </ul>                                                                                                  | <ul style="list-style-type: none"> <li>DC and RC samples have been geologically and geotechnically logged to a level of detail to support the appropriate Mineral Resource estimation, mining studies and metallurgical studies. Historical geological logs are available and good geological and grade correlation exists with different phases of drilling and field mapping undertaken from the companies involved and by EXG. . Specifically, each interval is visually inspected with a hand lens and the following parameters are recorded where observed: weathering, regolith, rock type, alteration, mineralisation, shearing/foliation and any other features that are present. All DC is logged for core loss, marked into metre intervals, orientated, structurally logged, geotechnically logged and logged with a hand lens with the following parameters recorded where observed: weathering, regolith, rock type, alteration, mineralisation, shearing/foliation and any other features that are present. This information is transferred electronically from the geologist to the database.</li> <li>All drill holes are completely logged. Where present the logging recorded the abundance of specific minerals or the amount of alteration (including weathering) using defined ranges. All DC is photographed both wet and dry after logging and before cutting.</li> <li>The entire lengths of RC holes were logged on a 1m interval basis, i.e. 100% of the drilling is logged, and where no sample was returned due to voids (or potentially lost sample) it is logged and recorded as such. Drill core was logged over its entire length and any core loss or voids intersected were recorded.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                      |

Review of the historical data confirms that the work undertaken is of sufficient quality to estimate the applicable JORC resource level.</p> <ul style="list-style-type: none"> <li>EXG RC samples submitted to the laboratory are sorted and reconciled against the submission documents. Excelsior inserts blanks and standards with blanks submitted in sample number sequence at 1 in 50 and standards submitted in sample number sequence at 1 in 20. The laboratory uses their own internal standards of 2 duplicates, 2 replicates, 2 standards, and 1 blank per</li> <li>50 fire assays. The laboratory also uses barren flushes on the pulveriser. No information is available for historic drilling, however, the position and tenor of gold mineralisation has been confirmed</li> <li>Samples are collected in uniquely pre-numbered calico bags. For EXG, in the field every 10th metre from the bulk sample port on the cone splitter is bagged and placed in order on the ground with other samples. This sample is then used for collection of field duplicates via riffle splitting. RC field duplicate samples are collected after results are received from the original sample assay. Generally, field duplicates are only collected where the original assay result is equal to or greater than 0.1g/t Au. The field duplicates are submitted to the laboratory for the standard assay process. The laboratory is blind to the original sample number. For DC, no core duplicates (i.e. half core) have been collected or submitted. No historical information is available from old data, however, EXG has twinned specific historical holes within each resource to confirm the old drilling results.</li> <li>For EXG, the sample sizes are considered to be appropriate for the type, style, thickness and consistency of mineralisation located at this project. The sample size is also appropriate for the sampling methodology employed and the gold grade ranges returned. Whilst no historical information is available EXG believes that the sample size was standard industry practice being collected by companies with known quality control methods and procedures. The samples collected by both EXG and previous operators are sufficient for the type, style, thickness and consistency of mineralisation.</li> </ul> |
| <b>Quality of assay data and laboratory tests</b> | <ul style="list-style-type: none"> <li>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</li> <li>For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</li> <li>Nature of quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.</li> </ul> | <ul style="list-style-type: none"> <li>The primary assay method used (Fire Assay by certified assay laboratories in Kalgoorlie and Perth) is designed to measure total gold in the sample. The laboratory procedures are appropriate for the testing of gold at this project given its mineralisation style. The technique involves using a 50g sample charge with a lead flux which is decomposed in a furnace with the prill being totally digested by 2 acids (HCl and HNO<sub>3</sub>) before measurement of the gold content by an AA machine.</li> <li>For EXG drilling, the QC procedures are industry best practice. The laboratory is accredited and uses its own certified reference material. The laboratory has 2 duplicates, 2 replicates, 1 standard and 1 blank per 50 fire assays. At the same time EXG submits blanks at the rate of 1 in 50 samples and certified reference material standards at the rate of 1 in 20 samples in the normal run of sample submission numbers. As part of normal procedures Excelsior examines all standards and blanks to ensure that they are within tolerances. Additionally, sample size, grind size and field duplicates are examined to ensure no bias to gold grade exists. No historical information is available but it can be assumed that the QAQC procedures used by the Kalgoorlie laboratories were of industry standard at that time</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

EXG used calico bags that are pre-numbered with a unique number to collect samples and logging of both DC and RC is via a digital logging system that uses fixed formats and standard codes. This information is emailed to the database administrator who imports the data via a standard procedure and the geologist then validates the data once in the database.</li> <li>Any errors recorded from the various validation processes are manually checked and correlated back to the original collection of data. If necessary field checks are made to confirm validation issues</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

As such the company has not report measured resources regardless of drill and sample density. The overall understanding of the mineralisation and controlling factors is well understood from the mapping and recent drilling of RC and DC holes. Geological and structural continuity is demonstrated in the available data sets.</li> <li>The use of historical drilling provides a level of uncertainty as the company cannot validate the QAQC data and downhole survey data. Hence EXG has twinned historical holes to confirm historical results and location of the mineralisation. This twinning has confirmed the historical data and combined with the new RC and DC drilling, high confidence in the geology and mineralisation is developed to support the JORC classified resource estimate.</li> <li>Different interpretations of the gold mineralisation wireframes have been undertaken to assess the influence on mineral resource estimation and mining economics. This work demonstrated that a possible +/- 10% difference exists between different lode interpretations. Where geological interpretation has a high degree of uncertainty it is classified as inferred regardless of modelling parameters.</li> <li>Detailed mapping, sampling of historical workings (including the existing open pits) provides confidence that the style of gold mineralisation is similar to other known deposits such as in the area. The mineral resource estimate process includes the building of a geological and structural framework that adds to the understanding of the mineralisation system. This framework is built from geological mapping, drill hole interpretation and geophysical images.</li> <li>Continuity of geology and structure can be identified and traced between drill holes by visual, geophysical and geochemical characteristics. The gold distribution within certain structures does display a high nugget effect; however gross high grade positions and plunge controls can be determined.</li> </ul> |

| <b>Discussion of relative accuracy/ confidence</b> | <ul style="list-style-type: none"> <li>• Where appropriate a statement of the relative accuracy and confidence level in the Mineral Resource estimate using an approach or procedure deemed appropriate by the Competent Person. For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the resource within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors that could affect the relative accuracy and confidence of the estimate.</li> <li>• The statement should specify whether it relates to global or local estimates, and, if local, state the relevant tonnages, which should be relevant to technical and economic evaluation. Documentation should include assumptions made and the procedures used.</li> <li>• These statements of relative accuracy and confidence of the estimate should be compared with production data, where available.</li> </ul> | <ul style="list-style-type: none"> <li>• The resource has been classified as Indicated or Inferred due to the reliance on various historical drill programmes undertaken between 1984 and 2002. Any blocks despite drill density being of a degree to demonstrate excellent grade and geological continuity that may have been classified as measured have been re-classified to Indicated or Inferred.</li> <li>• The block model estimate is a global resource estimate which has block sizes chosen at the expected "SMU" selection size. Block grades will tend to be smoothed between the drill hole sections but should represent the total contained tonnes and metal of the mineralisation.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## JORC Table 1 Checklist of Assessment and Reporting Criteria – VETTERSBURG SOUTH

### Section 1 Sampling techniques and data – Vetttersburg South

| Criteria                   | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Commentary                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Sampling techniques</b> | <ul style="list-style-type: none"> <li>• Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>• Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>• Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual</li> </ul> | <ul style="list-style-type: none"> <li>• The mineralisation was sampled by Reverse Circulation (RC) and Diamond Core (DC) drilling on variable drilling spacing ranging: <ul style="list-style-type: none"> <li>○ Vetttersburg South –from 30m x 30m grid spacing</li> </ul> </li> <li>• The holes were generally drilled to optimally intersect the targeted mineralized zones. It is noted that drilling has failed to adequately test for cross cutting structures that may or may not influence gold distribution.</li> <li>• The drill hole locations appear to have been designed to allow for spatial spread of samples across multiple mineralized zones and different rock types. All RC recovered samples were collected and passed through a cone splitter.</li> <li>• All RC drilling by were collected on one metre down hole intervals. The recovered samples were passed through a cone and/or a riffle splitter to collect a nominal 2.5kg – 3.5kg sample. Samples were composited over 2 to 4 metres and were taken to a Kalgoorlie contract laboratory. The sample was then prepared by standard fire assay techniques with a 20 to 50g charge.</li> </ul> |

| Criteria                                              | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Commentary                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Recent pit optimisation studies suggests economic cut-off grades are in the order of 0.5 to 0.85g/t Au</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Mining factors or assumptions</b>       | <ul style="list-style-type: none"> <li>Assumptions made regarding possible mining methods, minimum mining dimensions and internal (or, if applicable, external) mining dilution. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider potential mining methods, but the assumptions made regarding mining methods and parameters when estimating Mineral Resources may not always be rigorous. Where this is the case, this should be reported with an explanation of the basis of the mining assumptions made.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <ul style="list-style-type: none"> <li>Resources are reported at a cut-off grade of 0.6g/t Au to reflect possible economic grades via traditional open pit mining and processing via a 1mtpa (or larger) processing plant.</li> <li>Minimal mining widths of 2metres are assumed</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## JORC Table 1 Checklist of Assessment and Reporting Criteria – Burtville

### Section 1 Sampling Techniques and Data – Burtville

| Criteria                     | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sampling Techniques</b>   | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>Earliest RC drilling at Burtville used in the estimate was by Thames Mining NL (Thames), only 8 RC holes were used, limited information on the Thames drilling is reported by Aberfoyle Resources Ltd (Aberfoyle). Aberfoyle conducted RC drilling collecting 1m samples that were composited to 4m for analysis. Later programs riffle split the 1m sample into 2 samples, submitting 1 sample for analysis and retaining the duplicate sample onsite for future QAQC analysis.</li> <li>Gwalia Consolidated NL (Gwalia) RC drill cuttings were collected at 1m intervals and riffle split into 3kg samples for analysis.</li> <li>Sons of Gwalia Ltd (SOG) mined the Burtville deposit during the 1990s with RC drilling carried out by the site mining department and not reported to the Department of Mines. In the Crescent Gold Ltd (Crescent) Bankable Feasibility Study of January 2005 (WAMEX reference A070179 appendix), extensive geological and mining data acquired from SOG were validated against original records by an independent geologist.</li> <li>Early Crescent Drilling submitted 1m 3-4kg samples for analysis.</li> <li>Later drilling by FML collected 1m samples by cone splitter off the drill rig and submitted for analysis.</li> <li>Aberfoyle diamond core was sampled at 1m intervals. In areas of poor sample recovery core was sampled using a knife or hammer and chisel. Competent core was sawn, and one half submitted for analysis.</li> <li>Focus Diamond core was sampled at 1m intervals or to geological contacts, half core was submitted for assay.</li> <li>All sampling methods are used to produce representative sample of less than 3kg. Samples are selected to weigh less than 3kg to ensure total sample inclusion at the pulverisation stage.</li> <li>Genesis core and chip samples are crushed, dried and pulverised to a nominal 85% passing 75µm to produce a 40g or 50g sub sample for analysis by FA/AAS.</li> <li>Historical AC, RAB, RC and diamond sampling was carried out to industry standard at that time. Analysis methods include fire assay and unspecified methods.</li> </ul> |

The interpretation is built using local, structural, mineral, and alteration geology obtained from mapping, logging, and drill results. Confidence in the interpretation improved with increased data.</li> <li>The current Burtville resource has been interpreted from 20 diamond holes (DDH), and 2,298 reverse circulation (RC) holes.</li> <li>The gold mineralisation at Burtville is complex and is hosted within a granodiorite intrusive as well as via an extensive network of structurally controlled quartz veins. The stockwork of narrow quartz veins (1mm to 30cm) which cut the granodiorite, overlying sandstone and mafic units hosts a higher grade of gold compared with the alteration mineralisation seen in the surrounding granodiorite.</li> <li>The stockwork vein assemblage and associated alteration halo has been modelled using interpolants using leapfrog software. Drill holes were first downhole composited to 2m and a 0.3g/t cut-off grade used to generate the interpolants. A distance limiter of 20m was used to restrict wireframes extending too far from drill holes, and structural trends (established from visual observations of grade trends) to vary the anisotropy throughout the deposit.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

All domain wireframes are created using Leapfrog software and all subsequent estimation is completed using Datamine software. Lode wireframes are intersected with a validated drill database from which all RAB, air core, and erroneous drill holes have been removed. All remaining diamond, and RC samples are flagged with a domain identifier and composited to 1m with 0.3m minimum sample. Residual samples are distributed across adjacent component intervals. Composites are analysed for population outliers by domain and are topcut proximal to population disintegration. The top-cut process affects only 1-2% of the data. Variography is created for all domains with sufficient sample data. Output variograms are utilised in kriging neighbourhood analysis (KNA) to generate optimum parent block sizes and estimation parameters. Domains are estimated using ordinary kriging utilising the estimation parameters defined in the KNA as inputs. Grade is estimated into parent blocks only and all kriging quality metrics and search pass values are output. The maximum distance of extrapolation from last known data points for the inferred material is dependent on the geological continuity and confidence across the lode, but less than 40m for the deposit.</li> <li>No assumptions are made regarding the recovery of by-products for this Mineral Resource Estimation.</li> <li>No estimation of deleterious elements or non-grade variables is required.</li> <li>The model has been created using a parent cell size of 5m (East- West) x 5m (North-South) x 5m (vertical) optimised using quantitative kriging neighbourhood analysis. Sub-cells have been used at a resolution of 1m x 1m x1m to ensure high resolution at ore boundaries. The search distances are dictated by the range of each individual variogram but typically equate to 1-1.5 times the current 20x20m resource definition spacing. A 3rd pass nested search strategy is employed with the first pass always set to the full range of the variogram. The second pass is set at 2-3 times the variogram range with the final pass set at a factor large enough to ensure all blocks comprising the domain are estimated.</li> <li>No assumptions have been made regarding the modelling of selective mining units for this Mineral Resource Estimation</li> <li>No assumptions have been made regarding the correlation between variables for this Mineral Resource Estimation.</li> </ul> |

Drill holes were first downhole composited to 2m and a 0.3g/t cut-off grade used to generate the interpolants. A distance limiter of 20m was used to restrict wireframes extending too far from drill holes, and structural trends (established from visual observations of grade trends) to vary the anisotropy throughout the deposit.</li> <li>Samples with extreme high grades that bias the mean and positively skew the grade population within each domain are topcut to reduce the influence of high-grade outliers. Log probability plots and the coefficient of variation statistic are used to determine topcuts. Topcuts are typically set proximal to population disintegration.</li> <li>Several statistical and visual measures are used to validate the accuracy of the estimation. Volume variance between the wireframe domains and block model domains are assessed. A visual inspection of input composites is compared to the estimated block model in section for each domain. The mean grade of the block model is compared to the naïve and declustered mean grades of the composites by domain with any variance greater than 10% investigated. Swath plots are created by domain and sub-domain in the X, Y, Z, strike and cross strike directions and viewed holistically to vector into any problematic areas. Kriging efficiency, and slope results are reviewed by domain/sub-domain to give an indication of the quality of the estimate. Global change of support plots are created and reviewed for principal domains. The resource estimate was compared to historical production records (Barnicoat: 1989 – 1998, and FML, December 2012 – May 2013), both of which compared well with the final model.</li> </ul> |

| <b>Discussion of relative accuracy/confidence</b> | <ul style="list-style-type: none"> <li>Where appropriate a statement of the relative accuracy and confidence level in the Mineral Resource estimate using an approach or procedure deemed appropriate by the Competent Person. For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the resource within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors that could affect the relative accuracy and confidence of the estimate.</li> <li>The statement should specify whether it relates to global or local estimates, and, if local, state the relevant tonnages, which should be relevant to technical and economic evaluation. Documentation should include assumptions made and the procedures used.</li> <li>These statements of relative accuracy and confidence of the estimate should be compared with production data, where available</li> </ul> | <ul style="list-style-type: none"> <li>The Mineral Resource has been reported in accordance with the guidelines of the 2012 edition of the Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves.</li> <li>The resource estimate is a global estimate.</li> <li>The Mineral Resource estimate compared to past reconciliation data (within +/-5%).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## JORC Table 1 Checklist of Assessment and Reporting Criteria – Beasley Creek

### Section 1 Sampling Techniques and Data – Beasley Creek

| Criteria                   | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sampling Techniques</b> | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual</li> </ul> | <ul style="list-style-type: none"> <li>Surface and underground diamond core is HQ (63.5mm) or NQ (47.6mm) sized core, sampled to 1m intervals or geological boundaries where necessary and cut into half core. The upper or right-hand side of the core is routinely submitted for sample analysis, with each one metre of half core providing between 2.5 – 3kg of material as an assay sample. Minimum sample length is 0.30 m for DD core.</li> <li>RC chips are cone or riffle split and sampled into 1m intervals.</li> <li>All sampling methods are used to produce representative sample of less than 3kg. Samples are selected to weigh less than 3kg to ensure total sample inclusion at the pulverisation stage.</li> <li>Genesis core and chip samples are crushed, dried and pulverised to a nominal 90% passing 75µm to produce a 40g or 50g sub sample for analysis by FA/AAS.</li> <li>Historical AC, RAB, RC and diamond sampling was carried out to industry standard at that time. Analysis methods include fire assay and unspecified methods.</li> </ul> |

| Criteria                                              | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Estimation and modelling techniques</b> | <ul style="list-style-type: none"> <li><i>The nature and appropriateness of the estimation technique(s) applied and key assumptions, including treatment of extreme grade values, domaining, interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</i></li> <li><i>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</i></li> <li><i>The assumptions made regarding recovery of by-products.</i></li> <li><i>Estimation of deleterious elements or other non-grade variables of economic significance (e.g., sulphur for acid mine drainage characterization).</i></li> </ul> | <ul style="list-style-type: none"> <li>Mineralisation is domained based on geological continuity. All domain wireframes are created using Leapfrog software and all subsequent estimation is completed using Datamine software.</li> <li>Lode wireframes are intersected with a validated drill database from which all RAB, AC, VM, and erroneous drill holes have been removed. All remaining diamond and RC samples are flagged with a domain identifier and composited to 1m with a 0.3m minimum sample. Residual samples are distributed across adjacent component intervals.</li> <li>Composites are analysed for population outliers by domain and are topcut proximal to population disintegration. The top-cut process affects only 1-2% of the data.</li> <li>Two of the principal lodes exhibit bi/multi-modal grade populations. These internal populations are controlled by grade indicators based on inflection points derived from domain log probability plots from which indicator variograms are created. Categorical indicator kriging (CIK) is then used to sub-domain lodes with mixed populations. The block model used in the CIK estimation has blocks set at 1x1x1m to ensure sub-domain complexity is maintained then optimised</li> </ul>                                                                                                                      |

This model is then used to back flag the composite file with the defined sub-domain identifiers.</p> <ul style="list-style-type: none"> <li>Variography is created for all domains and sub-domains with sufficient sample data. Output variograms are utilised in kriging neighbourhood analysis (KNA) to generate optimum parent block sizes and estimation parameters.</li> <li>Domains and sub-domains are estimated using ordinary kriging utilising the estimation parameters defined in the KNA as inputs. Grade is estimated into parent blocks only and all kriging quality metrics and search pass values are output. The maximum distance of extrapolation from last known data points for the inferred material is dependent on the geological continuity and confidence across the lode, but less than 50m for the deposit.</li> <li>Search distances are dictated by the range of each individual variogram but typically equate to the current 30x30 m resource definition spacing. A 3-pass nested search strategy is employed with the first pass always set to the full range of the variogram. The second pass is set at 2 times the variogram range with the final pass set at a factor large enough to ensure all blocks comprising the domain are estimated.</li> <li>The Mineral Resource Estimation is checked against the previous block model estimations following any material update.</li> <li>No assumptions are made regarding the recovery of by-products for this Mineral Resource Estimation.</li> <li>No estimation of deleterious elements or non-grade variables is required.</li> <li>No assumptions have been made regarding the modelling of selective mining units for this Mineral Resource Estimation</li> <li>No assumptions have been made regarding the correlation between variables for this Mineral Resource Estimation.</li> <li>Mineralisation is partitioned into estimation domains relative to stratigraphic position, structural orientation, recorded lithology and specific alteration assemblage. The geological interpretation is initially created from drill data and later calibrated with mapping from open pit and underground exposures.</li> <li>Domains are estimated individually with search geometry and variography controlled by lode orientation and grade continuity respectively. Variogram major search directions are aligned to geologically interpreted high grade shoots.</li> <li>Categorical indicator kriging has been utilised to define sub-domains in lodes with mixed grade populations to limit the spread of high-grade mineralisation.</li> <li>Dynamic anisotropy has been employed on lodes exhibiting excessive undulation.</li> <li>Boundary analysis has been conducted on key lodes indicating hard boundaries should be maintained across domain and sub-domain contacts.</li> <li>Statistical and visual measures are used to validate the accuracy of the estimation.</li> <li>Volume variance between the wireframe domains and block model domains are assessed.</li> <li>A visual inspection of input composites is compared to the estimated block model in section for each domain.</li> <li>The mean grade of the block model is compared to the naïve and declustered mean grades of the composites by domain with any variance greater than 10% investigated.</li> <li>Swath plots are created by domain and sub-domain in the X, Y, Z, strike and cross strike directions and viewed holistically to vector into any problematic areas.</li> <li>Kriging efficiency, and slope results are reviewed by domain/sub-domain to give an indication of the quality of the estimate.</li> <li>Global change of support plots are created and reviewed for principal domains.</li> </ul> |
| <b>Moisture</b>                      | <ul style="list-style-type: none"> <li><i>Whether the tonnages are estimated on a dry basis or with natural moisture, and the method of determination of the moisture content.</i></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <ul style="list-style-type: none"> <li>Tonnages are estimated on a dry basis.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider the potential environmental impacts of the mining and processing operation. While at this stage the determination of potential environmental impacts, particularly for a greenfields project, may not always be well advanced, the status of early consideration of these potential environmental impacts should be reported. Where these aspects have not been considered this should be reported with an explanation of the environmental assumptions made.</li> </ul> | <ul style="list-style-type: none"> <li>Waste rock characterisation is on-going.</li> <li>Tailings from the deposit will be stored in an appropriate licensed tailings facility with a closure plan in place.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Mineral Resource Estimate for Conversion to Ore Reserves</b> | <ul style="list-style-type: none"> <li>Description of the Mineral Resource estimate used as a basis for the conversion to an Ore Reserve.</li> <li>Clear statement as to whether the Mineral Resources are reported additional to, or inclusive of, the Ore Reserves.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <ul style="list-style-type: none"> <li>The Beasley Creek Mineral Resource as reported May 2026. The Beasley Creek Mineral Resource estimate was completed using CIK with a parent block size of 1m x 2m x 1m and a 0.40g/t Au cut-off. The resource is classified under JORC (2012) as Measured (mined inventory), Indicated (<math>\geq 3</math> drill holes, <math>\geq 5</math> composites, <math>\leq 30\text{m} \times 30\text{m}</math> spacing), and Inferred (<math>\leq 60\text{m} \times 60\text{m}</math> spacing). Metallurgical recoveries are assumed to range between 92.67% and 97.74%. Metallurgical testing by GMD is ongoing.</li> <li>The Mineral Resources are reported inclusive of the Ore Reserve.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                                       | <p><i>specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</i></p> <ul style="list-style-type: none"> <li>• <i>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</i></li> <li>• <i>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information.</i></li> </ul> | <ul style="list-style-type: none"> <li>• RC percussion drill chips were collected through a cone splitter from the drill rig. The bulk sample from drilling was placed in neatly rows on the ground with the nominal 2-3kg calico split sub- sample placed on top of the corresponding sample.</li> <li>• RC chips were passed through a cone splitter to achieve a nominal sample weight of approximately 3kg. The splitter was levelled at the beginning of each hole. In the 2018 and 2019 drilling geological logging defined whether a sample was to be submitted as a 1m cone split sample or a 4m spear composite sample. Split samples (1m) were transferred to sample numbered calico bags for submission to the laboratory. Composite samples were spear sampled using a spear to obtain a small representative sample and deposited into numbered sample bags. Previous drill programs from 2017 and earlier have submitted 1m samples for assay taken from the drill rig for the entire hole length with no compositing of samples.</li> </ul> <p>Diamond Core Sampling</p> <ul style="list-style-type: none"> <li>• Diamond core was collected into standard plastic core trays. Down hole depths were marked onto wooden core blocks and stored in the trays.</li> <li>• The diamond core was marked up for sampling by the supervising geologist during the core logging process, with sample intervals determined by the presence of mineralisation and/or alteration. Whenever possible the cut-line was drawn parallel to and close to the down hole core orientation line to ensure the cut-line was consistent over the hole. The core was cut in half using an automatic core saw, with half-core samples submitted for analysis.</li> </ul> |
| <b>Drilling techniques</b>                            | <ul style="list-style-type: none"> <li>• <i>Drill type (e.g., core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g., core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</i></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <ul style="list-style-type: none"> <li>• RC drilling was conducted using a 5 3/8inch face sampling hammer for RC drilling.</li> <li>• At hole completion, downhole surveys for RC holes were completed at a 10m interval by using True North Seeking Gyro tool. Otherwise, a single shot Eastman camera downhole survey was used either "in-rod" or "open hole".</li> <li>• Diamond core was drilled at NQ2/HQ size. All drill core was oriented where competent by the drilling contractor using an Ezy-mark or similar system.</li> <li>• At hole completion diamond holes were survey using a single shot tool at a range of intervals between 20m and 50m, averaging 30m.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

The Karridale mineralisation is hosted in an interpreted half graben on the SE side of a large Granodiorite intrusion. The mineralisation is hosted primarily by the shallow NW dipping shears depicted by mylonitic sediment packages with intense carb-sericite alteration and by some NW-SE subvertical veins.</li> <li>• The logging of sheared to mylonitic zones, quartz veining and/or carbonate-sericitic alteration guided the primary interpretation so that it was not solely controlled by mineralisation.</li> <li>• The mineralised geological interpretation was completed using Seequent Leapfrog software on a section-by-section basis. An approximate 0.5g/t Au value was used to guide the interpretation.</li> <li>• Minor deviation only of the lode geometry was noticed between drill holes along strike and down-dip.</li> <li>• A number of steeply dipping NW striking cross fault features were identified and modelled. An apparent increase in grade was noted at the intersections of these cross faults and the shallow NW dipping lodes. The contacts of these intersections were considered a dilatational contacts with sharing of grades along the contact. Although in the flatter structures a grade dependent search was used to limit the influence of the high grades.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Sampling techniques</b> | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>This report relates to results from Reverse Circulation (RC) and diamond core (DDH) drilling.</li> <li>Wedge has been drilled by various companies over the years and this report contains information on holes drilled by Focus Minerals Ltd (FML); Teck Explorations Ltd (Teck) and Hillmin Gold Mines Pty Ltd (Hillmin), which was renamed Ashton Gold Mines Pty Ltd (Ashton) in October 1989. This was dissolved in December 1990 with all rights and obligations assumed by Ashton Gold (WA) Ltd. Metex Resources NL (Metex) subsequently acquired the tenement and conducted 2 drill campaigns.</li> <li>Teck collected 1m samples in plastic bags from the drill rig cyclone and were split for assay. The 1m splits were combined to form 2m samples which were assayed for gold by AAS methods. Where anomalous AAS results were returned, 1m samples were submitted for fire assay.</li> <li>Hillmin/Ashton collected 1m RC samples via a riffle splitter. A spear sample was taken of the intervals in the form of 2m and 4m composites for subsequent drill programs. Where composite assays exceeded 0.25 ppm Au, the corresponding 1m sample was submitted.</li> <li>Ashton recorded duplicate samples in the assay files.</li> <li>Hillmin reported a comparison check between assay laboratories in a 1988 WAMEX report.</li> <li>Hillmin diamond core was sampled as either 4m filleted composites or a sawn core sampled to lithological contacts.</li> <li>Metex collected 1m samples split from the rig using a cyclone riffle splitter. A 4m composite sample was taken by spear sampling the 1m interval spoils. Resampling of the composite intervals where assay results were 0.1 ppm Au or greater was carried out on an individual 1m basis.</li> <li>The information of sampling techniques below applies to the drill holes drilled by Focus Minerals (FML) only.</li> <li>RC percussion drill chips were collected through a cyclone and in-line cone splitter under driller control.</li> <li>RC chips were passed through a cone splitter to achieve a sample weight of approximately 3kg. The splitter was levelled at the beginning of each hole using a bullseye level. The spoils were collected in green bags or heaped neatly on the ground at 1m intervals. Samples for assay were collected in pre-numbered calico bags.</li> <li>Standards of appropriate grade were inserted into the RC and DDH sample runs at a rate of 1 per</li> <li>20. No blanks were used as many of the primary samples on the project recorded assays below or close to the detection limit making the role of the blank superfluous. Instead, gold geochemical standards with low expected values were utilised regularly.</li> <li>RC samples were collected as either a 4m composite taken from the bulk 1m sample or the 1m cyclone cone split sample. Where 4m composites returned a grade over 0.2ppm the corresponding cyclone split sample was collected.</li> <li>Diamond core was sampled across identified zones of mineralisation by site geologists, the sample widths varied between a nominal minimum of 0.3m and a nominal maximum of 1m.</li> <li>The diamond core was marked up for sampling by the supervising geologist during the core logging process, with sample intervals determined by the presence of mineralisation and/or alteration. Sample intervals did not overlap zones of core loss. The core was cut in half using an automatic core saw. Samples for assay were put into pre-numbered calico bags.</li> <li>At the assay laboratory all calico bagged assay samples were oven dried, core samples (only) crushed to a nominal 10mm using a jaw crusher and weighed. Samples in excess of 3kg in weight were riffle split to achieve a maximum 3kg sample weight before being pulverized to 90% passing 75µm.</li> </ul> |

| <b>Database integrity</b>                  | <ul style="list-style-type: none"> <li>Measures taken to ensure that data has not been corrupted by, for example, transcription or keying errors, between its initial collection and its use for Mineral Resource estimation purposes.</li> <li>Data validation procedures used.</li> </ul>                                                                                                                                                                                                                                                                                                 | <ul style="list-style-type: none"> <li>Data was geologically logged electronically; collar and downhole surveys were also received electronically as was the laboratory analysis results. These electronic files were loaded into an acQuire database by the company in-house Database Administrator. Data was routinely extracted to Microsoft Access during the drilling program for validation by the geologist in charge of the project.</li> <li>FML's database is a Microsoft SQL Server database (acQuire), which is case sensitive, relational and normalised to the Third Normal Form. Because of normalisation, the following data integrity categories exist:</li> <li>Entity Integrity: no duplicate rows in a table, eliminated redundancy and chance of error.</li> <li>Domain Integrity: Enforces valid entries for a given column by restricting the type, the format or a range of values.</li> <li>Referential Integrity: Rows cannot be deleted which are used by other records.</li> <li>User-Defined Integrity: business rules enforced by acQuire and validation codes set up by FML.</li> <li>Additionally, in-house validation scripts are routinely run in acQuire on FML's database and they include the following checks:</li> <li>Missing collar information <ul style="list-style-type: none"> <li>Missing logging, sampling, downhole survey data and hole diameter</li> <li>Overlapping intervals in geological logging, sampling, down hole surveys</li> <li>Checks for character data in numeric fields.</li> </ul> </li> <li>Data extracted from the database were validated visually in GEOVIA Surpac software and ARANZ Geo Leapfrog software. Also, when loading the data any errors regarding missing values and overlaps are highlighted.</li> <li>Historic data has been validated against WAMEX reports where possible.</li> </ul> |

|                                             | <ul style="list-style-type: none"> <li>The assumptions made regarding recovery of by-products.</li> <li>Estimation of deleterious elements or other non-grade variables of economic significance (e.g., sulphur for acid mine drainage characterization).</li> <li>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</li> <li>Any assumptions behind modelling of selective mining units.</li> <li>Any assumptions about correlation between variables.</li> <li>Description of how the geological interpretation was used to control the resource estimates.</li> <li>Discussion of basis for using or not using grade cutting or capping.</li> <li>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</li> </ul> | <ul style="list-style-type: none"> <li>A review of histograms, probability plots and mean/variance plots for the main lode domain revealed outlier sample values. A maximum top-cut of 25g/t Au and an average of 10g/t Au was used for the different lodes, with assays above the top-cut set to the top-cut value.</li> <li>Variograms were modelled in Supervisor for the main lode and one of the smaller lodes that had the largest number of samples. Other minor lodes shared the minor lode variogram.</li> <li>GEOVIA Surpac Software was used for the estimation and modelling process. The model was created in GDA 94 grid co-ordinates. Block sizes for the model were 12.5m in Y, 12.5m in X and 5m in Z direction. Sub celling of the parent blocks was permitted to 1.562m in the Y direction, 1.562m in the X direction and 1.25m in the Z direction. Sub-blocking was used to best fill the wireframes and inherit the grade of the parent block. No rotation was applied to the orientation of the blocks.</li> <li>Block size is approximately ½ of the average drill hole spacing along strike and across strike was selected to best fill the wireframe volumes.</li> <li>An Ordinary Kriging (OK) estimation technique was selected and used the variograms modelled in Supervisor.</li> <li>The main lode was estimated using a minimum (6) and maximum (20) samples were selected based on a Kriging Neighbourhood analysis in Supervisor.</li> <li>The smaller lodes were estimated using a minimum (6) and maximum (14) samples.</li> <li>An elliptical search was used based on range/ratio of the Variograms.</li> <li>Three search passes were run in order to fill the block model with estimated Au values. After each search pass the search range was increased and the minimum number of samples was decreased.</li> <li>The estimate was validated by a number of methods. An initial visual review was done by comparing estimated blocks and raw drill holes.</li> <li>Tonnage weighted mean grades were compared for the lodes with no major differences.</li> <li>Swath plots of drill hole values and estimated Au grades by northing and RL were run and showed that the estimated grades honoured the trend of the drilling data.</li> <li>Available production figures for Wedge were used as a comparison with the estimated material within the pit shells. Production figures state 262,023t @ 2.53g/t Au HG ore was mined from the pits and 260,544t @ 2.51g/t of HG ore was Milled.</li> </ul> |

At this stage no Laverton claims have progressed to determined status.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                       |                   |                       |                   |        |                                             |       |              |                                                                 |       |               |                              |       |               |          |                                                                                                                                                                                                               |       |               |                  |              |       |               |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |  |  |          |       |               |
| Exploration done by other parties       | <ul style="list-style-type: none"><li>Euro area has been historically mined since 1895 when gold was first discovered in the region. Euro North was mined by shaft and drive from 1898 to 1911 with a recorded production of 35,707 ounces of gold from 94,826 tonnes of ore at an average grade of 11.7g/t Au.</li><li>Euro South was mined by Crescent Gold from an open pit between 2009 and 2010 producing 843kt at 1.42g/t Au for 38.6koz.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                       |                   |                       |                   |        |                                             |       |              |                                                                 |       |               |                              |       |               |          |                                                                                                                                                                                                               |       |               |                  |              |       |               |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |  |  |          |       |               |
| Geology                                 | <ul style="list-style-type: none"><li>The Euro trend covers a sequence of tholeiitic meta-basalt flows with intrusive dolerite plus minor felsic porphyries and discontinuous banded chert interflows sediments. The prospect is bound to the west by the Craigiemore - Mary Mac banded chert/BIF and to the east and N-OS striking AMAG high that may be another BIF sequence or mafic unit. A sedimentary sequence of greywackes and conglomerates, unconformably overlying the eastern side of the packages controlled by the Childe – Harold Fault Zone. These clastics units may be a local equivalent of Wallaby type conglomerates. North north west striking shears and cross cutting moderate west dipping faults have been sericite-carb-chl altered. Mineralisation is strongly associated with alteration more so than quartz veining.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                       |                   |                       |                   |        |                                             |       |              |                                                                 |       |               |                              |       |               |          |                                                                                                                                                                                                               |       |               |                  |              |       |               |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |  |  |          |       |               |
| Drill hole Information                  | <ul style="list-style-type: none"><li>Historic drilling information has been validated against publicly available WAMEX reports. Not all drill holes can be found referenced in the WAMEX reports. However, cross-checking of original drill surveys was verified against the database. Most of these holes were drilled in the excavated pit area and has been depleted from the reported resource.</li></ul> <p>EURO SOUTH WAMEX Reference:</p> <table><tr><th>Company</th><th>Drill Hole ID</th><th>WAMEX Report A-Number</th><th>WAMEX Report Date</th></tr><tr><td rowspan="3">Ashton</td><td>E48, E49, E50, E51, E53, E54, E55, E57, E58</td><td>17955</td><td>January 1990</td></tr><tr><td>E62, E63, E64, E65, E66, E67, E68, E69, E70, E71, E72, E74, E75</td><td>33653</td><td>February 1991</td></tr><tr><td>E80, E81, E82, E83, E84, E85</td><td>35633</td><td>December 1991</td></tr><tr><td>Dominion</td><td>EURC004, EURC005, EURC006, EURC007, EURC008, EURC009, EURC011, EURC012, EURC013, EURC014, EURC015, EURC016, EURC017, EURC018, EURC019, EURC021, EURC022, EURC023, EURC024, EURC025, EURC026, EURC027, EURC028</td><td>43121</td><td>November 1994</td></tr><tr><td>Crescent Gold NL</td><td>GTDE5, GTDE7</td><td>69877</td><td>November 2004</td></tr><tr><td></td><td>SL02, SL04, SL05, SL07, SL09, SL12, SL13, SL14_SOUTHLAV, SL15_SOUTHLAV, SL16_SOUTHLAV, SL17_SOUTHLAV, SL18_SOUTHLAV, SL19_SOUTHLAV, SL20_SOUTHLAV, SL21_SOUTHLAV, SL22_SOUTHLAV, SL24, SL25, SL26_SOUTHLAV, SL27_SOUTHLAV, SL29, SL30_SOUTHLAV, SL31_SOUTHLAV, SL32, SL33_SOUTHLAV, SL34_SOUTHLAV, SL35_SOUTHLAV, SL36_SOUTHLAV, SL37_SOUTHLAV, SL40_SOUTHLAV, SL41_SOUTHLAV, SL42_SOUTHLAV, SL44_SOUTHLAV, SL45_SOUTHLAV, SL46_SOUTHLAV, SL50, SL51, SL55, SL57, SL58, SL59, SL60, SL62, SL63, SL64, SL65, SL66, SL67, SL68, SL69, SL70</td><td></td><td></td></tr><tr><td></td><td>EURRC001</td><td>74177</td><td>December 2006</td></tr></table> | Company               | Drill Hole ID     | WAMEX Report A-Number | WAMEX Report Date | Ashton | E48, E49, E50, E51, E53, E54, E55, E57, E58 | 17955 | January 1990 | E62, E63, E64, E65, E66, E67, E68, E69, E70, E71, E72, E74, E75 | 33653 | February 1991 | E80, E81, E82, E83, E84, E85 | 35633 | December 1991 | Dominion | EURC004, EURC005, EURC006, EURC007, EURC008, EURC009, EURC011, EURC012, EURC013, EURC014, EURC015, EURC016, EURC017, EURC018, EURC019, EURC021, EURC022, EURC023, EURC024, EURC025, EURC026, EURC027, EURC028 | 43121 | November 1994 | Crescent Gold NL | GTDE5, GTDE7 | 69877 | November 2004 |  | SL02, SL04, SL05, SL07, SL09, SL12, SL13, SL14_SOUTHLAV, SL15_SOUTHLAV, SL16_SOUTHLAV, SL17_SOUTHLAV, SL18_SOUTHLAV, SL19_SOUTHLAV, SL20_SOUTHLAV, SL21_SOUTHLAV, SL22_SOUTHLAV, SL24, SL25, SL26_SOUTHLAV, SL27_SOUTHLAV, SL29, SL30_SOUTHLAV, SL31_SOUTHLAV, SL32, SL33_SOUTHLAV, SL34_SOUTHLAV, SL35_SOUTHLAV, SL36_SOUTHLAV, SL37_SOUTHLAV, SL40_SOUTHLAV, SL41_SOUTHLAV, SL42_SOUTHLAV, SL44_SOUTHLAV, SL45_SOUTHLAV, SL46_SOUTHLAV, SL50, SL51, SL55, SL57, SL58, SL59, SL60, SL62, SL63, SL64, SL65, SL66, SL67, SL68, SL69, SL70 |  |  |  | EURRC001 | 74177 | December 2006 |
