

5<sup>th</sup> May 2026

## Resource and Reserve update

# Resources total 18.9Moz, including 4.4Moz in Reserves

**Resources per share increase by 28%; Reserves per share increase by 18%**

---

## HIGHLIGHTS

- ▶ Genesis is exclusively focused on the prolific Leonora / Laverton District in Western Australia, with 18.9Moz in Resources and 4.4Moz in Reserves close to existing processing facilities and other production infrastructure
- ▶ Large Reserve position underpins the “ASPIRE 500\*” accelerated growth strategy, with updated multi-year production and cost assumptions (including FY27 guidance) on track for September quarter 2026 release

## Resources at 31<sup>st</sup> December 2025

- ▶ **Mineral Resources of 18.9Moz** at 31<sup>st</sup> December 2025 (14.7Moz at 31<sup>st</sup> December 2024), **an increase of 29%** after mining depletion of 243koz
- ▶ Details include:
  - Maiden Genesis’ Focus Laverton Resource of 3.9Moz @ 1.7g/t<sup>1,2</sup>
  - Gwalia up 7% to 4.8Moz and Jupiter up 19% to 740koz (after mining depletion), Bruno Lewis up 22% to 440koz
- ▶ **Resources per share grew by 28%**

## Reserves at 31<sup>st</sup> December 2025

- ▶ **Ore Reserves of 4.4Moz** at 31<sup>st</sup> December 2025 (3.7Moz at 31<sup>st</sup> December 2024), **an increase of 19%** after mining depletion of 243koz
- ▶ Ore Reserves are **estimated conservatively using an assumed gold price of A\$2,800/oz** compared with the current spot price of ~A\$6,400/oz, **maintaining Genesis’ focus on high-margin, high quality ounces**
- ▶ Details include:
  - Maiden Genesis’ Focus Laverton Reserve of 591koz @ 1.2g/t<sup>3</sup>
  - Tower Hill up 10% to 1.1Moz; Driven by significantly lower unit milling costs through planned new Tower Hill mill
  - Bruno Lewis up 65% to 280koz
- ▶ **Reserves per share grew by 18%**

## Further organic growth opportunities

- ▶ Exploration spend steadily increasing (FY24 A\$14.7m, FY25 A\$19.0m, FY26 budget A\$40-50m)
- ▶ **Host of strong intersections reported outside Reserves** (refer today’s ASX Announcement “Outstanding Leonora drilling paves way for more organic growth”; **Ongoing drill success and outstanding cash flow from operations to motivate a meaningful increase in the FY27 exploration budget**
- ▶ **Extensive opportunities to grow Reserves via conversion of the 14.5Moz of Resources not in Reserves<sup>4</sup>**
- ▶ **Pro-forma Resources 21.3Moz and Reserves 5.4Moz**, including A\$639m “bolt-on” acquisition of Magnetic Resources (2.4Moz Resources and 1.0Moz Reserves)<sup>5</sup> - On track for June 2026 completion
- ▶ Maiden Genesis’ Resources and Reserves for the Magnetic assets will be released as part of the updated multi-year plan in the September quarter 2026

Executive Chair Raleigh Finlayson Raleigh Finlayson said:

*“The significant increases in resources and reserves per share shows the value we are creating by growing and upgrading our inventory.*

*“With our milling capacity set to grow substantially as the new Tower Hill plant approaches construction, we are increasing our focus on converting more of our 19Moz resource to reserves while also stepping up exploration outside the resource boundaries.*

*“We have more than doubled our exploration budget for this financial year and we are committed to a further meaningful increase in FY27.*

*“We believe that this is money well-invested, with much of it being used to target the exploration sweet spot of resource-to-reserve conversion. This will deliver more inventory for our growing milling capacity while creating value and reducing risk in the process”.*

### Corporate structure

|                                    |                                     |

\* Aspirational goal (not a production target)

1. Focus Laverton project acquired in June 2025 for A\$250m cash

2. Focus Laverton Resources comprise Karridale, Beasley Creek, Chatterbox Trend, Lancefield-Wedge and Laverton Other;

3. Focus Laverton Reserves comprise Karridale, Beasley Creek and Lancefield;

4. Derived by subtracting Ore Reserves from Mineral Resources;

5. Refer ASX Announcement 16<sup>th</sup> February 2026 “GMD bolsters production outlook with recommended offer for Magnetic”.

## Overview - Resources and Reserves

Genesis Minerals Limited (Genesis) (ASX: GMD) is pleased to announce updated Mineral Resources and Ore Reserves estimates. At 31<sup>st</sup> December 2025, **Group Resources stand at 18.9Moz** and **Group Reserves stand at 4.4Moz**.

*Table 1. Summary of Group Mineral Resources\**

| Mineral Resource |            |            |             |
|------------------|------------|------------|-------------|
|                  | Mt         | g/t        | Moz         |
| Measured         | 0.4        | 3.6        | 0.045       |
| Indicated        | 190        | 2.2        | 13.4        |
| Inferred         | 96         | 1.8        | 5.5         |
| <b>Total</b>     | <b>280</b> | <b>2.1</b> | <b>18.9</b> |

*Table 2. Summary of Group Ore Reserves\**

| Ore Reserves |           |            |            |
|--------------|-----------|------------|------------|
|              | Mt        | g/t        | Moz        |
| Proved       | -         | -          | -          |
| Probable     | 73        | 1.9        | 4.4        |
| <b>Total</b> | <b>73</b> | <b>1.9</b> | <b>4.4</b> |

\*Rounding errors may occur

The Reserve position underpins the “ASPIRE 500” accelerated growth strategy, with updated multi-year production and cost assumptions (including FY27 guidance) on track for the September quarter 2026.

The update includes **Genesis’ maiden Resource and Reserve estimates for the Focus Laverton assets**, acquired in June 2025 for A\$250m cash i.e. for no increase in the share count.

Focus Laverton is a large, underexplored project within 30km of the operating Laverton mill. There are multiple open-pit mining opportunities with maiden Genesis Reserves reported at Karridale, Beasley Creek and Lancefield. Site infrastructure includes 42km of haul roads, workshops and sheds, and a camp.

Exploration upside is significant. Despite significant prospectivity and proximity to multi-million-ounce mines at Granny Smith and Sunrise Dam, the tenure has been near dormant for more than a decade under previous ownership. Genesis has commenced drilling at Beasley Creek with results pending.

*Figure 1. Beasley Creek long section - First cab off the rank\**

\*Drill results extracted from Genesis' ASX announcements on 26<sup>th</sup> May 2025 "Genesis eyes further growth in production and cashflow with acquisition of Laverton Gold Project " and 1<sup>st</sup> September 2025 "Drilling results at Laverton and Leonora support organic growth".

## MINERAL RESOURCE UPDATE

The updated 2026 Genesis Mineral Resources Estimate is 280Mt @ 2.1g/t Au for 18.9Moz which is a significant increase from the previous 2025 Mineral Resources Estimate of 210Mt @ 2.2g/t Au for 14.7Moz, with a slight increase in the updated Mineral Resources Estimate reported by Genesis on 26<sup>th</sup> May 2025 of 280Mt @ 2.1g/t for 18.7oz, post the acquisition of the Laverton Gold Project.

The material information for these new Mineral Resources models is included in following sections. All other Mineral Resources have been the subject of previous ASX Announcements. The updated Mineral Resources Estimates are for the Gwalia, Ulysses, Admiral Group, Jupiter, Cardinia West, Beasley Creek and Hub Projects.

Key changes to the Mineral Resources Estimate from 2025 are:

- ▶ Increase of 300koz in the Gwalia Mineral Resources Estimate (MRE) after depletion;
- ▶ Admiral - MRE increased by 50koz including 61koz of depletion;
- ▶ Bruno-Lewis and Kyte resource has increase Indicated ounces by 33% from extensive grade control and near mine drilling; – MRE updated with an increase of 80koz;
- ▶ Jupiter MRE increased 120koz (from inferred resource) following review and re-estimation ;
- ▶ Hub MRE decreased by 46koz from mining depletion.

Mineral Resources across other Leonora assets, Laverton and Bardoc remain unchanged from 2024 Mineral Resources.

The significant changes in the estimated 2026 Mineral Resources compared with the Company's 2025 Mineral Resource estimates are shown below:

Figure 9: Changes in Resources - 2025 vs 2026

## ORE RESERVE UPDATE

Genesis has completed an updated Ore Reserves Estimate based on the 2026 Mineral Resources Estimate. The updated 2026 Reserve Estimate is **72Mt @ 1.9g/t Au for 4.4Moz**, which is up from the previous 2025 Ore Reserves Estimate of 54Mt @ 2.1g/t Au for 3.7Moz, with a slight increase in the updated Ore Reserve Estimate reported by Genesis on 26<sup>th</sup> May 2025 of 68Mt @ 1.9g/t for 4.2Moz, post the acquisition of the Laverton Gold Project.

The Ore Reserves Estimate is supported by existing operational performance and costs, Pre-Feasibility or Feasibility level studies and forms a sub-set of the Company's Production Target.

A detailed financial model was generated for the Ore Reserves on a standalone basis and has been used to determine the economic parameters for the Ore Reserves Estimate.

The Ore Reserves have been completed in accordance with the 2012 JORC Code. The Ore Reserves are based on the Measured and Indicated portion of the Mineral Resources Estimate. The Ore Reserves Estimate represents the portion of the Production Target based on Measured and Indicated Mineral Resources only. No Inferred material has been included in the Ore Reserves Estimate. The table below presents a summary of the Proved and Probable Ore Reserves based on the mine designs using an A\$2,800/oz gold price optimisation.

*Table 7. Genesis 2026 Ore Reserves Estimate by Project*

| Project               | Tonnes<br>(000s) | Proved<br>Grade<br>(g/t Au) | Ounces<br>(000s) | Tonnes<br>(000s) | Probable<br>Grade<br>(g/t Au) | Ounces<br>(000s) | Tonnes<br>(000s) | Total<br>Grade<br>(g/t Au) | Ounces<br>(000s) |

**Notes:**

All figures reported to two significant figures. Rounding errors may occur.

Ore Reserves are based on a gold price of A\$2,800/ounce

Key changes to the Ore Reserves Estimate include:

- ▶ Depletion in Ore Reserves from active mining areas:
  - Gwalia 115koz
  - Admiral 61koz
  - Hub 33koz
  - Ulysses 28koz
  - Jupiter 6koz
- ▶ Increase in Tower Hill Ore Reserve from 1.0Moz to 1.1Moz driven by:
  - Updated design and scheduling

- Improved operating costs through an upgraded Tower Hill Process Plant
- Increase in Bruno-Lewis Open Pit Ore Reserve from 170koz to 280koz driven by:
  - Significant infill and near mine extensional drilling
  - Geological interpretation and re-estimation
- Increase in Gwalia Underground Ore Reserve from 1.1Moz to 1.2Moz driven by:
  - Significant infill and near mine extensional drilling
  - Geological interpretation and re-estimation
- Increase in Ulysses Underground Ore Reserve from 240koz to 310koz driven by:
  - Conversion of Open Pit Ore Reserve into Underground Ore Reserve
  - Significant infill and near mine extensional drilling
- Removal of Ulysses Open Pit Ore Reserve driven by:
  - Conversion of Open Pit Reserve into Underground Ore Reserve

Ore Reserves across the remaining Leonora, Laverton, Redcliffe and Bardoc assets remain unchanged from the 2025 Ore Reserve estimation.

Figure 10. Change in Ore Reserve Estimate – 2025 vs 2026

## MATERIAL INFORMATION SUMMARIES

The Mineral Resources and Ore Reserves Estimates have been reported in accordance with the 2012 Edition of the 'Australasian Code for reporting of Exploration Results, Mineral Resources and Ore Reserves' (JORC Code 2012) and the ASX Listing Rules.

Material information summaries are provided within this announcement for the Gwalia, Ulysses, Admiral, Hub, Jupiter, Bruno-Lewis, Tower Hill and Beasley Creek Mineral Resources and Ore Reserve Estimates.

Material information summaries relating to the Karridale and Lancefield Pits can be found in Genesis' previous ASX Announcement 'Reserves rise to 3.7Moz, underpinning ASPIRE 400 strategy', dated 8<sup>th</sup> April 2025.

Material information summaries relating to the Westralia and Puzzle Pits can be found in Genesis' previous ASX Announcement 'Acquisition of Laverton Gold Project', dated 26<sup>th</sup> May 2025.

Material information summaries relating to the Harbour Lights, Aphrodite, Zoroastrian, Excelsior and Bardoc Satellite Pits can be found in the previous ASX Announcement 'Revised: Reporting on St Barbara Leonora Projects', dated 20<sup>th</sup> April 2023.

Material information summaries relating to Orient Well can be found in the previous ASX Announcement 'Completion of the Leonora acquisition elevates Genesis to a leading Australian gold house', dated 3<sup>rd</sup> July 2023.

## GWALIA

### RESOURCES & RESERVES SUMMARY

Genesis reports a Mineral Resources Estimate of **31Mt at 4.8g/t for 4.8Moz** and Ore Reserves Estimate of **7.2Mt at 5.0g/t for 1.2Moz**. Key changes to the previously reported Mineral Resources include:

- ▶ Updated geological interpretations with new drilling, estimation parameters, classification, and reporting constraints have been applied; and
- ▶ Underground mining depletion of 115koz @ 5.8g/t.

The in situ resources have been reported within an optimised pit shell at a 0.50g/t Au cut-off based on Measured, Indicated and Inferred Mineral Resources. The underground Mineral Resources have been reported within Mineable Shape Optimisations (MSOs) generated at a 2.5g/t Au cut-off, with no assumptions made for mining dilution.

Key changes to the previous Ore Reserve Estimate include:

- ▶ Underground mining depletion of 115koz @ 5.8g/t; and
- ▶ Updated cost drivers based on reconciled actuals and budget pricing.

### GWALIA MINERAL RESOURCES

#### Geology and Geological Interpretation

Gold mineralisation at Gwalia consists of gold-bearing quartz-carbonate veins that vary in size from millimetres to metres thick. These veins are folded, stretched (boudinaged), and laminated, and they sit inside a wide zone of strongly deformed, east-dipping basalt schist called the "mine schist". The mine schist grades gradually over 10–20 metres into less-deformed basaltic rocks, where pillow basalts are often visible. The area shows signs of extensional shearing (stretching deformation) visible in the open pit walls.

In the mineralised domains, the rocks display tight isoclinal folds, rootless folds, and boudinaged veins — all evidence of very ductile (plastic-like) deformation. The main foliation (called S1b) runs parallel to the axes of these folded gold-bearing veins/lodes. Microscope studies show that most of the gold occurs in centimetre to metre-scale smoky grey quartz-carbonate veins that are folded and boudinaged. Gold appears as visible free grains and tiny inclusions inside scattered sulphide minerals. Some quartz veins have extremely high gold grades (>100g/t Au). The major ore lodes show consistent gold grades along their length (strike) and depth (down dip). Later, irregular barren (gold-poor) white quartz veins cut across the earlier deformed ones.

Higher gold grades are mostly restricted to southeast-plunging folded lodes and veins. Gold does not spread out into the surrounding strongly foliated mine schist, even where strain (deformation intensity) is highest. This pattern indicates the gold was deposited in the veins before the main folding and shearing event occurred. The later deformation folded and stretched the veins but did not significantly remobilise or redistribute the gold into the surrounding schist.

## **Drilling Techniques**

Surface and underground diamond drill holes used NQ2 (50.6mm) sized core (standard tubes). Surface drill holes have been down hole surveyed by north seeking gyro and underground drill holes have been surveyed by single shot electronic camera. Surface holes are orientated using a Reflex ACT II RD orientation tool.

## **Sampling and sub-sampling techniques**

Diamond core samples were cut in half longitudinally, with intervals from 0.3 to 1.3m in length but were predominantly aligned to 1m intervals or with sample boundaries which respected geological contacts. Reverse circulation (RC) drilling samples were collected in 1m downhole intervals by passing through a cyclone, a collection box and then dropping through a cone splitter. All RC sub-samples were collected over one metre downhole intervals and had an averaged mass of 3-4kg.

## **Sample Analysis Method**

Sample preparation included oven drying (105°C), crushing (<6mm), pulverising (P90% passing 75µm) and split to obtain a 50-gram catchweight. Analysis for gold only was carried out by fire assay fusion technique with atomic absorption spectroscopy (AAS) finish. Blanks and certified reference material (CRM) standards were inserted in each sample batch at a rate of 1:50 for exploration RC and diamond drilling (DD), and 1:20 for grade control (GC) drilling. Laboratory pulp grind and crush checks were typically requested at a ratio of 1:50 or less. Best practice QAQC methods for all drilling operations and the treatment and analysis of samples have been implemented and adhered to.

## **Estimation Methodology**

All domains were estimated using ordinary kriging (OK) for grade estimation from a resource dataset of RC and diamond drilling only. Samples have been flagged by estimation domain wireframes, assigned a unique domain identifier, and composited to 1m. Composites have been analysed for grade outliers and topcut as appropriate to minimise the Coefficient of Variation (CV). Variograms for well supported domains were created to analyse nugget values and the spatial continuity of the data, and act as inputs to the OK estimations. All estimation parameters have been derived from Kriging Neighbourhood Analysis (KNA). Where lodes exhibit bi/multi-model grade populations, categorical indicator kriging (CIK) has been utilised to generate sub-domains within lodes prior to grade estimation using OK.

The block model used in the CIK estimation has blocks set at 1x1x2m to ensure sub-domain complexity is maintained, then optimised and re-blocked to the parent block size of 5mx5mx5m for parent cell size grade estimation with nested search passes employed informed by variogram ranges.

The models have been depleted for historical mining where appropriate and bulk density has been assigned by weathering profile. Estimated grades have been validated both visually and statistically to ensure conformance to input sample data.

## **Cut-off Grades**

The in situ resources have been reported within an optimised pit shell at a 0.50g/t Au cut-off based on Measured, Indicated and Inferred Mineral Resources. The underground Mineral Resource has been reported within mining shape optimisation (MSO) underground shells generated at 2.5g/t cut-off. No assumptions have been made for mining dilution.

## **Resource Classification**

The Gwalia Mineral Resource is classified as Measured, Indicated or Inferred by domain based on a combination of physical and estimation quality metrics including mining exposure, drill spacing, search pass, kriging efficiency / slope / variance, grade and geological continuity. Mineralisation has been categorised as Measured if it has been exposed by mining (open pit or development). Indicated material is assigned if drill spacing is supported by up to 50x50m but no greater than 80m, search pass either 1 or 2, established grade and geological continuity, broadly positive kriging efficiency

and >20% slope. Inferred material is drill spacing supported by ~80x80m with established geological continuity. All other mineralisation is assigned a Potential Mineral Resource category.

### Mining Assumptions

The mining method is underground, open stoping with paste fill. The mine is in production with an extensive mining history.

### Metallurgical Assumptions

Metallurgical recovery is modelled on the observed relationship between the head grade and recovery. The average modelled metallurgical recovery over the Ore Reserve mine plan is 95.8%.

### Other Modifying Factors

No modifying factors are applied to the Mineral Resource.

### GWALIA ORE RESERVES

The Gwalia Ore Reserves are calculated on a A\$2,800/oz gold price assumption. The Ore Reserve includes only Proved and Probable classifications. The economically mineable component of the Measured Mineral Resource has been classified as a Proved Ore Reserve while the economically mineable component of the Indicated Mineral Resource has been classified as a Probable Ore Reserve.

*Table 1. Gwalia Ore Reserve*

| Project   | Proved      |             |             | Probable    |             |             | Proved + Probable |             |             |
|-----------|-------------|-------------|-------------|-------------|-------------|-------------|-------------------|-------------|-------------|
|           | Tonnes (kt) | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) | Tonnes (kt)       | Grade (g/t) | Ounce (koz) |
| Gwalia UG | -           | -           | -           | 7,200       | 5.0         | 1,200       | 7,200             | 5.0         | 1,200       |

*Table 11. Gwalia Underground Comparison to Previous Ore Reserve*

| Project   | Reserve at 31 Dec 2024 |             |             | Reserve at 31 Dec 2025 |             |             | Variance    |             |             |
|-----------|------------------------|-------------|-------------|------------------------|-------------|-------------|-------------|-------------|-------------|
|           | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) |
| Gwalia UG | 6,800                  | 5.3         | 1,100       | 7,200                  | 5.0         | 1,200       | 400         | -0.3        | 100         |

The Ore Reserves includes a Probable classification estimated based on the economically mineable component of the Measured and Indicated Mineral Resource. No inferred Mineral Resources are included in the Ore Reserves.

Figure 11. Gwalia Underground Life of Mine

## Mining Method and Assumptions

The Gwalia Ore Reserve has been estimated based on detailed mine development and stope designs. Modifying factors for dilution and mining recovery have been applied post geological interrogation to generate the final diluted and recovered Ore Reserve.

The Gwalia Mine is in full production with an extensive production history. Mining methods referenced in this report are currently in practice on site or have been subject to trial mining. Reconciliation results and production history show this mining method to be well matched to the ore body.

Stope size, development placement and ground support strategies have been designed in line with recommendations from experienced geotechnical personnel and external subject matter experts. Grade control drilling is completed in advance of production with most stopes to be mined in the next two years already grade control drilled.

The following mining assumptions have been applied:

- ▶ A review of dilution was conducted of past stope performance, and no discernible difference was noted between lodes or depth below surface. Correlation was found to stope size and values used range from 28% for stopes less than 5kt to 16% for stopes exceeding 25kt. The average of the estimated dilution for all stopes in the Ore Reserve is 22%;
- ▶ A 92% mining recovery factor has been applied to triple-lift and double-lift long-hole open stopes. A 90% mining recovery factor has been applied to single-lift long-hole open stopes. These factors are consistent with reconciled actual performance;
- ▶ The profiles of development excavations have been designed inclusive of 10% overbreak. No further dilution factors or mining recovery factors have been applied to development ore; and
- ▶ A global minimum mining width of 3m is used. While the ore body width generally exceeds the minimum mining width, where the ore body is narrower stoping outlines are designed to honour the minimum width and include planned dilution.

## Processing Method & Assumptions

All Gwalia ore is trucked to the Gwalia processing plant. The processing plant is located at Genesis Minerals Leonora Operations and consists of a three-stage crushing circuit, single-stage milling circuit, hybrid carbon-in-leach (CIL) circuit with one designated leach tank, and seven adsorption tanks. Gold is recovered from activated carbon into concentrated solution via a split AARL-type elution circuit. Electrowinning and smelting are conducted in an adjacent secure gold room. The tailings from the process are thickened and pumped to a paddock-type tailings storage facility with multi-spigot distribution.

Metallurgical recovery is modelled on the observed relationship between the head grade and recovery. The average of the modelled metallurgical recovery over the Ore Reserve mine plan is 96.3%.

On completion of the new 3.5-4.0Mtpa Tower Hill Process Plant construction, Gwalia Ore will be processed through the new plant which will comprise of single stage crushing, Semi-Autogenous Grinding, Ball Milling and Pebble Crushing (SABC) comminution circuit, followed by a conventional gravity and carbon-in-leach (CIL) process.

The technology associated with the processing of Gwalia ore is currently in operation and is based on industry standard practices.

## Cut-Off Grade

The cut-off grade assumptions are derived from cost and production estimates developed for the Life of Mine forecast. A 3-stage approach was taken in evaluating the Ore Reserve estimate:

1. A break-even type of analysis was used to determine the cut-off grades for generating stope shapes, with the following derived estimates:
  - 3.5g/t Stope Evaluation Cut-Off Grade - used to define the extent of economic stoping areas on a level;
  - 2.8g/t Stope Only Cut-Off Grade - used to define additional stopes that can be mined without extra development and without delaying the main mining sequence; and
  - 0.6g/t Process Only Cut-Off Grade - used to differentiate between development ore and development waste.
2. Level economics was completed using activity unit costs derived from current and future costings for all development and production activities.
3. Time-based assessment was applied to ensure production profile covers all associated fixed running costs.

## Tenure

The Ore Reserves estimated in this report are located on tenements owned by the subsidiaries of Genesis Minerals Limited.

## Environmental Permitting & Approvals

The Gwalia mine is currently compliant with all environmental regulatory instruments under the *Environmental Protection Act 1986 (WA)* and *Mining Act 1978 (WA)*.

All external reporting against the environmental licenses and tenements is recorded and available on the relevant regulators' websites.

## Infrastructure

The infrastructure requirements of the stoping methods used are either already in place or have been accounted for in the Life of Mine evaluation on which the project costings are based. The capital and operating costs of extending the

ventilation infrastructure to support truck haulage down to the base of the Ore Reserve have been included in the economic evaluation which demonstrates the economic viability of the Ore Reserve.

Existing equipment required for the mining and processing of the Ore Reserve is in place and operational. It is located on tenements owned by the subsidiaries of Genesis Minerals Limited. The infrastructure includes, but is not limited to:

- ▶ Dedicated gas and diesel power station;
- ▶ Water supply from three sources to provide redundancy;
- ▶ Processing plant;
- ▶ Mine development;
- ▶ Underground power and dewatering infrastructure;
- ▶ Workshop facilities on surface and underground;
- ▶ Ventilation fans and refrigeration plant;
- ▶ Paste fill plant;
- ▶ Camp facilities; and
- ▶ Access to public roads and airstrips.

## **Costs**

All costs used in the estimation of the Ore Reserves are based on the Life of Mine plan and operating costs are estimated as part of the internal budgeting process and approved by the Genesis Minerals Limited Board.

The Gwalia underground mining costs are well known given it is an ongoing operation based on current established contracts and forward estimates built on historical spends vs future production levels. Where pertinent, supplier budget estimates have been used.

Accommodation is based on current rates for accommodation facilities in Leonora by third parties. Flights are based on current chartered rates incurred by Genesis through the Leonora airport.

Power, processing, general and administration costs are based on actual operating costs incurred at the Gwalia operation.

A gold price of A\$2,800/oz has been used in all calculations.

Exchange rates are provided by Genesis Finance.

Costs associated with ore treatment and transport have been included in the cost modelling completed for the project-based on the Life of Mine plan.

Royalties have been included at the WA government royalty of 2.5% of gold produced. A third-party royalty is also applied to the Gwalia tenements at 1.5% of gold produced.

## **Revenue Factors**

The Gwalia Ore Reserve is based on a A\$2,800/oz gold price.

## **Economic Outcomes**

The Ore Reserve Estimate is based on a Feasibility level of accuracy with inputs from mining, processing, transportation, sustaining capital and contingencies scheduled and costed to generate the Ore Reserve cost model.

The Ore Reserve Estimate is economic based on the assumed commodity price and cost estimation, and the Competent Person is satisfied that the project economics that make up the Ore Reserve are suitable, based on the mine design,

modifying factors, assumptions, and environment.

Sensitivity analysis has indicated that the project drivers are gold price, mining and metallurgical recovery, followed by operating expenditure.

## ULYSSES

### RESOURCES & RESERVES SUMMARY

Genesis reports an updated Mineral Resource Estimate of **5.9Mt at 3.8g/t for 0.72Moz** and Underground Ore Reserve Estimate of **2.8Mt at 3.4g/t for 0.31Moz** for Ulysses. The open pit Ore Reserve Estimate has been removed given a large proportion of the previous Ore Reserve has now been included in the increased Underground Ore Reserve. Key changes to Ulysses previously reported Mineral Resource include:

- ▶ Underground mining depletion of 28koz; and
- ▶ Updated geological interpretations with new drilling, estimation parameters, classification, and reporting constraints have been applied.

The in situ resources have been reported within an optimised pit shell at a 0.40g/t Au cut-off based on Measured, Indicated and Inferred Mineral resources. The underground Mineral Resource has been reported within MSO underground shells generated at 2.0g/t cut-off. Previously the Mineral Resource was reported using different cut-off grades to represent open pit and underground Mineral Resources.

Key changes to the previous Ore Reserve Estimate includes:

- ▶ Underground mining depletion of 28koz;
- ▶ Updated cost drivers based on reconciled actuals and budget pricing;
- ▶ Inclusion of previously reported Open Pit Ore Reserve; and
- ▶ Removal of entire Open Pit Ore Reserve

### ULYSSES MINERAL RESOURCES

#### Geology and Geological Interpretation

The Ulysses deposit lies within the Archaean-aged Norseman to Wiluna greenstone belt. Host rocks comprise a sequence of dolerite and basalt units. Gold mineralisation is associated with a strongly altered, distinctive assemblage of biotite-sericite-albite-pyrite ± carbonate alteration and quartz veining located within a regionally extensive WNW trending shear zone termed the Ulysses Shear. Depth of complete oxidation is approximately 30m to 40m with depth to fresh rock occurring approximately 45 to 60 metres below surface.

Within the Ulysses shear zone, discrete zones of mineralisation are typically 1-8m thick and dip at 30-50° to the north-east. Several horizons of magnetic dolerite sills occur within the mafic stratigraphy at Ulysses. Where the main shear cuts through these units, local thickening and increased grade are evident and form plunging shoots with good continuity of grade and thickness over considerable plunge lengths. These high-grade plunging shoots are visually identifiable due to the strong pyrite-albite-biotite. They have been separately modelled and estimated to properly reflect the observed the high-grade continuity.

Drilling at Ulysses extends to a maximum depth of 520m below surface. The mineralisation has been interpreted and estimated to that depth and the mineralisation remains open over much of the 2.7km strike length of the deposit.

## Drilling Techniques

The Ulysses Mineral Resource has principally been defined by a combination of diamond and reverse circulation (RC) drilling. Rotary air blast (RAB) and air core (AC) holes have been completed in the resource area but have been excluded from both the geological interpretation and the MRE.

Diamond holes typically used NQ (47.6mm) and HQ (63.5mm) sized core. Recovery is recorded by the drillers on core blocks and compared to the measurements of the core by the geologist. Recovery is generally very high (>95%) with no significant sample recovery problems typically recorded. Core is oriented using orientation tools to facilitate structural measurements and cut along a plane passing through the basal orientation mark using a diamond saw.

RC holes used mainly 5½" reverse circulation face sampling hammers with samples typically taken at one metre intervals through a cone splitter. Most samples were dry, but where wet samples were encountered, these were allowed to dry before being split by company personnel.

## Sampling and sub-sampling techniques

For RC drilling, a face-sampling hammer was used with samples collected at 1m intervals from mineralised zones with composite sampling of 4m or 5m in unmineralised rocks. Samples were collected through rig-mounted or free-standing riffle or cone splitters. Samples were reported to have been kept dry throughout the mineralised zones and visually determined recoveries were good.

Diamond drilling was completed using a HQ or NQ drilling bit for all diamond holes. Sampling intervals are selected by the geologist and are split with half core samples bagged and sent for assay.

## Sample Analysis Method

Diamond core samples were cut in half longitudinally, with intervals from 0.3 to 1.3m in length but were predominantly aligned to 1m intervals or with sample boundaries which respected geological contacts. RC drilling samples were collected in 1m downhole intervals by passing through a cyclone, a collection box and then dropping through a cone splitter. All RC sub-samples were collected over one metre downhole intervals and had an averaged mass of 3-4kg.

## Estimation Methodology

All domains were estimated using ordinary kriging for grade estimation from a resource dataset of RC and Diamond drilling only. Samples have been flagged by estimation domain wireframes, assigned a unique domain identifier, and composited to 1m. Composites have been analysed for grade outliers and topcut as appropriate to minimise the Coefficient of Variation (CV). Variograms for well supported domains were created to analyse nugget values and the spatial continuity of the data and act as inputs to the OK estimations. All estimation parameters have been derived from Kriging Neighbourhood Analysis (KNA). Where lodes exhibit bi/multi-model grade populations, categorical indicator kriging (CIK) has been utilised to generate sub-domains within lodes prior to grade estimation using ordinary kriging.

The block model used in the CIK estimation has blocks set at 1x2x1m to ensure sub-domain complexity is maintained then optimised and re-blocked to the parent block size of 5mx10mx5m for parent cell size grade estimation, with a nested search passes employed informed by variogram ranges.

The models have been depleted for historical mining where appropriate and bulk density has been assigned by weathering profile and on a lode-by-lode basis. Estimated grades have been validated both visually and statistically to ensure conformance to input sample data.

## Cut-off Grades

The in situ resources have been reported within an optimised pit shell at a 0.40g/t Au cut-off based on Measured, Indicated and Inferred Mineral resources. The underground resource has been reported within MSO underground shells generated

at 2.0g/t cut-off. No assumptions have been made for mining dilution.

## Resource Classification

The Ulysses Resource is classified as Measured, Indicated, Inferred, or Potential (Unclassified) using the guidelines of the JORC Code (2012). The categories are assigned based on a combination of physical and estimation quality metrics including mining exposure, drill spacing, kriging metrics, grade and geological continuity. Resource categories are manually assigned to individual lodes via digitised string to the RESCAT attribute. Mineralisation has been categorised as Measured only if it has been exposed by mining. Indicated material is assigned if drill spacing is supported by up to 40mx40m, established grade and geological continuity from drilling and/or historical pit mapping. Inferred material is drill spacing supported by 40mx40m to ~80x80m with limited geological continuity. All other mineralisation is assigned a Potential resource category.

## Metallurgical Assumptions

Extensive metallurgical test work has been carried out as part of the Feasibility Study at Ulysses confirming that the ore is amenable to conventional cyanide leaching. Ongoing test work by Genesis has confirmed gold recoveries from primary ore to be ~88% to 91%.

## Other Modifying Factors

No modifying factors are applied to the Mineral Resource. The reported Mineral Resource has been depleted to account for existing open pit mining.

## ULYSSES ORE RESERVES

The Ulysses Underground Ore Reserves have been calculated on a A\$2,800/oz gold price assumption. The Ore Reserve includes only Proved and Probable classifications. The economically mineable component of the Measured Mineral Resource has been classified as a Proved Ore Reserve while the economically mineable component of the Indicated Mineral Resource has been classified as a Probable Ore Reserve. Updates to the Ulysses Underground Ore Reserves include minor mining depletion and design changes, mining rates, and cost assumption refinements based on additional data collated since the 2024 reserves release.

*Table 12. Ulysses Ore Reserve*

| Project    | Proved      |             |             | Probable    |             |             | Proved +Probable |             |             |

| Ulysses OP | 1,400                  | 2.3         | 110         | -                      | -           | -           | -1,400      | -2.3        | -110        |
| Ulysses UG | 2,000                  | 3.7         | 240         | 2,800                  | 3.4         | 310         | 800         | -0.3        | 70          |

The Ore Reserves includes Probable classification estimated based on the economically mineable component of the Measured and Indicated Mineral Resource. No inferred Mineral Resources are included in the Ore Reserves.

Figure 12. Ulysses Underground Reserve Design

## Mining Method and Assumptions

Mineral Resource material was converted to Ore Reserves after completing an optimisation process, detailed mine design, and schedule and associated financial assessment.

The Ulysses Underground Ore Reserve is to be mined using conventional underground mining methods. The mining consists of Longhole Open Stopping (LHOS) on 12.5m level spacing with voids remaining open and in situ rock rib and sill pillars used for stability. Mining operations will be undertaken by an experienced and reputable mining contractor using a conventional fleet of twin boom jumbo drills, 76mm production drills, 17-tonne loaders and 63-65-tonne trucks.

The mining methods chosen are well known and widely used in the local mining industry, and production rates and costing can be predicted with a suitable degree of accuracy. Access to the mine portal exists via the pre-existing Ulysses West open pit.

Underground designs are based on geotechnical parameters provided by independent geotechnical consultants, Operational Geotechs.

The following assumptions were applied:

- ▶ Stopping was designed within the recommended HR parameters of 4.4;
- ▶ Stope parameters used in the underground Ore Reserves are 12.5m floor to floor level spacing (height), maximum 30m strike length, staggered rib pillars with 0.5:1 – 1:1 pillar ratios above a minimum 5m width and with sill pillars located on a maximum 100m spacing;
- ▶ Underground grade control will be carried out using diamond drill holes from dedicated hanging wall diamond drill drives. The costs have been based on estimated drilling requirements and recent underground diamond drilling rates;
- ▶ Mineral Resources used for optimisation are those described in this document/
- ▶ A cut-off grade of 1.7g/t applied as the basis for initial stope design, with all designs assessed by detailed financial analysis to confirm their viability in consideration of the works required to access and extract them. The assessed designs were used to determine the economic extent of the orebody;
- ▶ A cut-off grade of 0.81/t applied to development activities within the economic extent of the orebody as defined above, considering the cost incurred relating to processing, haulage, and general and administration (G&A);
- ▶ A 10% dilution factor was applied to capital mine development (i.e., declines, level accesses and associated development) at zero grade;
- ▶ Dilution was applied to operating mine development (i.e., ore drives) through increasing the planned cross-sectional area of the design by 9%, then interrogating against the block model;
- ▶ Stope dilution was included in optimisation shapes at a 1.15m depth of overbreak, reflecting geotechnical

recommendations for dilution. The overbreak represents dilution of approximately 25% on the average width stopes at Ulysses;

- ▶ In situ stope recovery is assumed at 90% after exclusion of rib and sill pillars; and
- ▶ A minimum mining width of 2.5m was applied to underground stopes.

Inferred Mineral Resources were included in initial stope optimisation processes, however any Inferred material contained within final underground designs was treated as waste at zero grade.

### **Processing Method & Assumptions**

All ore is assumed to be carted along the Goldfields Highway for processing through the existing Gwalia processing facility located 36km north of Ulysses. This is a standard CIL circuit suitable for treatment of the Ulysses Ore.

All underground material is fresh and based on test work it was determined that a grade and grind size-based formula would be used for Ore Reserve estimates, averaging 88.6% through the Gwalia processing facility at a 90µm grind size.

No deleterious elements were identified from the mineralogical/metallurgical assessments that impact on process selection.

### **Cut-Off Grade**

High confidence costs assumptions, revenue factors and physicals form the basis for Cut Off Grade (COG) calculations.

Mill recovery is estimated based on metallurgical test work carried out as part of the Feasibility Study.

A gold price of A\$2,800 / oz was assumed for the Cut Off Grade calculations.

The underground COG of 1.7g/t was used as the basis for initial stope design, with all designs assessed by detailed financial analysis to confirm their viability in consideration to the works required to access and extract them.

### **Tenure**

The Project is located on a single granted Mining Lease M40/166 which is wholly-owned by Ulysses Mining Pty Ltd, a subsidiary of Genesis Minerals Limited.

### **Environmental Permitting and Approvals**

All base line environmental and heritage assessments have been completed with no known impacts on the mining operation for Ulysses. The Ulysses UG project has all necessary approvals obtained to commence mining operations including:

- ▶ Mining Proposal & Closure Plan;
- ▶ Clearing Permit;
- ▶ Works Approval for water supply & discharge;
- ▶ 5C Licence to abstract water;
- ▶ Explosives Storage Licence;
- ▶ Project Management Plan, and
- ▶ Mining Operational Notice.

### **Infrastructure**

Infrastructure for Ulysses Underground is now in place, with all requirements met for commencement of mining, including provision of:

- ▶ Offices;
- ▶ Workshops;
- ▶ ERT and First Aid Facilities;
- ▶ Power Station;
- ▶ IT & Communications;
- ▶ Fuel;
- ▶ Dewatering and Water Supply;
- ▶ Compressors;
- ▶ Laydown Area; and
- ▶ Site Access Roads.

Further expenditure is considered for additional surface infrastructure requirements commensurate with the ramp up of underground mining rates.

Labour will be sourced primarily on a fly-in fly-out basis through the Leonora airport, housing the workforce at accommodation facilities in the Leonora township. Where possible, labour and subcontracted services will be sourced from local communities.

Power is provided by on site by diesel generators.

Water will be sourced initially through pit lake water at Ulysses Central with any additional water requirements filled through pit lakes at the ABCDK mining area and Orient Well.

## **Costs**

All costs used in the estimation of the Ulysses Ore Reserves are based on the Life of Mine plan and operating costs are estimated as part of the internal budgeting process and approved by the Genesis Minerals Limited Board.

Ulysses underground mining costs are well known as is it an ongoing operation based on current established contracts and forward estimates built on historical spends vs future production levels. Where pertinent, supplier budget estimates have been used.

Accommodation is based on current rates for accommodation facilities in Leonora by third parties. Flights are based on current chartered rates incurred by Genesis Minerals through the Leonora airport.

Power, processing, and general and administration costs are based on actual operating costs incurred at the Gwalia operation.

A gold price of A\$2,800/oz has been used in all calculations.

Exchange rates are provided by Genesis Finance.

A state royalty of 2.5% and a third-party royalty of 0.9% are payable on gold produced.

## **Revenue Factors**

The Ulysses Ore Reserve is based on a A\$2,800/oz gold price.

## **Economic Outcomes**

The Ulysses Ore Reserve Estimate is based on a Feasibility level of accuracy with inputs from mining, processing,

transportation, sustaining capital and contingencies scheduled and costed to generate the Ore Reserve cost model.

The Ore Reserve is economic based on the assumed commodity price and cost estimation, and the Competent Person is satisfied that the project economics that make up the Ore Reserve are suitable based on the mine design, modifying factors, assumptions, and environment.

Sensitivity analysis has indicated that the project drivers are gold price, mining and metallurgical recovery followed by operating expenditure.

## ADMIRAL GROUP

### RESOURCES & RESERVES SUMMARY

Genesis reports a Mineral Resource Estimate of **7.3Mt at 1.5g/t for 0.35Moz** and Ore Reserve Estimate of **1.8Mt at 1.3g/t for 74koz** for the Admiral Group.

The in situ resources have been reported within an optimised pit shell at a 0.40g/t Au cut-off based on Measured, Indicated and Inferred Mineral resources. Previously the OP resource was reported using only a cut-off grade of 0.5g/t and a maximum depth of 130m below surface.

Key changes to the previously reported Admiral Group Mineral Resource and Ore Reserve:

- Updated cost driver based on reconciled actuals and budgeted pricing; and
- Mining depletion of 61koz.

### ADMIRAL GROUP MINERAL RESOURCES

#### Geology and Geological Interpretation

The Admiral Group of deposits lies within the Archaean-aged Norseman to Wiluna greenstone belt. Host rocks comprise a sequence of dolerite and basalt units. Gold mineralisation is associated with a strongly altered, distinctive assemblage of biotite-sericite-albite-pyrite±carbonate alteration and quartz veining located within regionally extensive north south trending shear zones which take the same name as the deposit they are located on. Depth of complete oxidation varies from 1m to 30m with depth to fresh rock varying from 5 to 50m.

Within the shear zones, discrete zones of mineralisation are typically 2-8m in thickness and dip at 30-50° to the east. Several horizons of magnetic dolerite sills occur within the mafic stratigraphy at ABCDK. Where the main shear cuts through these units, local thickening and increased grade are evident. The zones are visually distinct and typically display sharp boundaries to the mineralisation.

On the northern contact of the dolerite sill with the pillow basalts at Admiral, Clark and Butterfly there is an intense zone of shearing which runs parallel to the lithological contact dipping at 50-60° to the north. This shear is mineralised over 1.5km strike from the Admiral deposit in the west through Clark to Butterfly in the east. The mineralisation on this contact is referred to as the Hercules shear.

Mineralisation within the Hercules Shear is typically 5m to 12m wide and hosted within highly foliated basalts with intense quartz/carbonate/sericite alteration and associated sulphides.

Drilling in the area extends to a maximum depth of 300m below surface. The mineralisation has been interpreted and estimated to that depth and the mineralisation remains open over much of the 1.5km strike length of the deposits. The ABCDK mining centre comprises Admiral, Clark, Clark North, Butterfly, Butterfly North, Danluce and King.

## **Drilling Techniques**

The Admiral Group of Mineral Resources has primarily been defined by Diamond (DD) and Reverse Circulation (RC) drilling. Diamond drilling has been completed at NQ2 (47mm) and HQ3 (64mm) core sizes and oriented to facilitate the acquisition of structural data. Drill hole collars were surveyed in MGA coordinates using RTK GPS. RC holes have been surveyed with multi shot at intervals ranging from 10m to 50m. DD holes have been surveyed with a down-hole survey method of magnetic gyroscope or magnetic camera, which are captured for most of the hole depth.

## **Sampling and sub-sampling techniques**

For RC drilling, a face-sampling hammer was used with samples collected at 1m intervals from mineralised zones with composite sampling of 4m or 5m in unmineralised rocks. Samples were collected through rig-mounted or free-standing riffle or cone splitters. Samples were reported to have been kept dry throughout the mineralised zones and visually determined recoveries were good.

Diamond drilling was completed using a HQ or NQ drilling bit for all diamond holes. Sampling intervals are selected by the geologist and are split with half core samples bagged and sent for assay.

## **Sample Analysis Method**

Samples from the majority of drilling were assayed at contract laboratories using a fire assay technique. Drilling completed by Genesis up until December 2021 was assayed at Intertek laboratories in Perth using a 50g fire assay. After December 2021 all samples from Admiral Group deposits have been analysed by Chrysos PhotonAssay™ at the Intertek laboratory in Perth.

Quality Assurance and Quality Control (QAQC) data was collected from Genesis drilling and included the use of blanks, certified standards and field duplicates. Detailed review of the QAQC data determined that the results were satisfactory, and that the drilling database was suitable for resource estimation. Drilling by previous operators has limited quality control data and is limited to field duplicates and inter-laboratory checks.

The Genesis infill drilling supports historically drilled data and validates it for use in this Mineral Resource Estimate.

## **Estimation Methodology**

Gold grades have been estimated using ordinary kriging (OK) using 1m composited and top-cut drillhole data, comprising reverse circulation and diamond drillholes only. The ABCDK mineralisation system comprises 115 modelled mineralisation domains, which utilise a lower modelling cut-off of 0.2g/t gold. The estimation strategy has been defined based on data support and a review of the kriging neighbourhood analysis for major domains. The estimation uses a staged search strategy, with the first search distance generally the aligned to the modelled variogram (using between 8-16 sample), then expanding to two times (maintaining the same sample pairs) and finally a third pass designed to estimate the remaining unestimated blocks. The parent block size reflects half the drill spacing and sub-celled to accurately reflect the volume of the modelled domains. Density values have been assigned based on weathering surfaces and lithology. The estimation has been verified through available production reconciliation and resources and grade control metrics where close spaced drill data becomes available.

## **Cut-off Grades**

The in situ Mineral Resources have been reported within an optimised pit shell at a 0.4g/t Au cut-off based on Measured, Indicated and Inferred Mineral resources.

## **Resource Classification**

The recent infill drilling has confirmed the continuity and extent of the high grade shoots within the deposit with most holes intersecting mineralisation where planned.

The portion of the deposit defined by detailed drilling at 20m by 20m spacing and displaying good continuity of grade and predictable geometry has been classified as Indicated Mineral Resource.

The peripheral areas of lodes and areas which were drilled at 40-50m centres or sparsely drilled or were variably mineralised were classified as Inferred Mineral Resource. This was generally extrapolated to up to 50m past drill hole intersections.

### Metallurgical Assumptions

Extensive metallurgical test work has been carried out as part of the Feasibility Study at the Admiral Deposits confirming that the ore is amenable to conventional cyanide leaching. Ongoing test work by Genesis has confirmed gold recoveries from primary ore to be ~88% to 92%.

### Other Modifying Factors

No modifying factors are applied to the Mineral Resource. The reported Mineral Resource has been depleted to account for existing open pit mining.

## ADMIRAL GROUP ORE RESERVES

The Admiral Group Ore Reserves have been estimated on a A\$2,800/oz gold price assumption. The Ore Reserve includes only Probable classifications. The economically mineable component of the Indicated Mineral Resource has been classified as a Probable Ore Reserve. Updates to the Admiral Group Reserve include mining depletion and minor pit design changes, mining rates and cost assumption refinements based on additional data collated since the 2025 reserves release.

*Table 14: Admiral Pit Group Ore Reserve*

| Project       | Proved      |             |             | Probable    |             |             | Proved +Probable |             |             |
|---------------|-------------|-------------|-------------|-------------|-------------|-------------|------------------|-------------|-------------|
|               | Tonnes (kt) | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) | Tonnes (kt)      | Grade (g/t) | Ounce (koz) |
| Admiral Group | -           | -           | -           | 1,800       | 1.3         | 74          | 1,800            | 1.3         | 74          |

*Table 15: Admiral Pit Group Comparison to Previous Ore Reserve*

| Project       | Reserve at 31 Dec 2024 |             |             | Reserve at 31 Dec 2025 |             |             | Variance    |             |             |
|---------------|------------------------|-------------|-------------|------------------------|-------------|-------------|-------------|-------------|-------------|
|               | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) |
| Admiral Group | 1,700                  | 1.5         | 80          | 1,800                  | 1.3         | 74          | 100         | -0.2        | -6          |

The Ore Reserves includes Probable classification estimated based on the economically mineable component of the Measured and Indicated Mineral Resource. No inferred Mineral Resources are included in the Ore Reserves.

*Figure 13. Admiral Group Reserve Pit Designs*

### **Mining Method and Assumptions**

The Admiral Group Reserves will be mined using 140t rear dump trucks 100t hydraulic excavator mining fleets, using drill and blast on 5 m benches and excavators operating on 2.5m flitches. Haul road widths of 27m for dual access roads and 16m for single access roads were used. Minimum mining width of 20m was used for cutbacks and pit benches with the exceptions of goodbye cuts that will be top loaded.

Mining of the pit will be carried out by Genesis Mining Services Pty Ltd (GMS), Genesis' 'internal mining contractor', utilising its own mining fleet under an 'owner-operator' model. Leasing and ownership costs have been allocated across the life of the equipment asset. Operating costs for the fleet have been built up utilising the OEM guidance as well as reconciled actuals, incorporating the operating strategy under the GMS ownership.

Final pit limits were determined from pit optimisations using Whittle Four-X software with inputs from the diluted resource model, geotechnical parameters, metal prices, metallurgical recoveries, royalties, modifying mining factors and operating costs. Appropriate optimisation shells were selected to suit the operation, from which detailed pit designs and mine schedules were completed.

Ore dilution was modelled by applying a modifying factor to the ore tonnes of the resource model. The modifying factor ranged from 15%-18% and was based on the geometry and grade distribution of the mineral lodes and the selective mining unit (SMU). Similarly, mining recovery was modelled by applying a recovery factor ranging from 90% to 95% on contained metal in the resource model above COG.

A detailed Geotechnical assessment of the Admiral Group deposit was carried out by geotechnical consultants (Operational Geotechs) which recommended the wall angles and bench heights based upon weathering zones and wall orientation. These recommendations were used as the basis for the pit designs and are reviewed regularly by the Genesis geotechnical teams.

### **Processing Method & Assumptions**

The Admiral Group ore is free milling and will primarily be processed through the existing Gwalia processing plant. If opportunities arise or strategy dictates, then some Admiral ore may be processed at the Laverton processing plant. The Gwalia processing plant consists of a 1.4Mtpa crushing and grinding circuit followed by a conventional gravity recovery and carbon-in-leach (CIL) circuit. The 3.0Mtpa Laverton processing plant was commissioned in late March 2018 and includes a Semi-Autogenous Grinding, Ball Milling and Pebble Crushing (SABC) comminution circuit followed by a conventional gravity and carbon-in-leach (CIL) process.

A series of metallurgical test work programs have been undertaken for the Admiral Group deposit and these have been used as the basis for determining the milling recovery factors for each pit. Domains were established by zone (Admiral, Butterfly, Butterfly North, Clark, Danluce, King) and by weathering state (oxide, fresh). All metallurgical test work programs were conducted on representative mineralised composites prepared from either RC chips or diamond drill core. There are no known occurrences of deleterious elements. The average recoveries for the Admiral Group domains are as follows:

*Table 16. Admiral Group Metallurgical Recoveries*

|             | Mt Morgan 106um | Gwalia 90um |
|-------------|-----------------|-------------|
| Admiral     | 89.6%           | 90.6%       |
| Butterfly   | 87.6%           | 88.6%       |
| Clark       | 90.1%           | 90.2%       |
| Clark North | 88.1%           | 89.3%       |
| King        | 88.7%           | 89.7%       |

### **Cut-Off Grade**

Cut Off Grades were derived from cost estimates developed for the Feasibility Study. The cut-off grade used to define ore is the breakeven grade for variable processing and ore haulage costs and a share of the fixed costs for general and administration (G&A) through the Gwalia and Laverton processing plants. A cut-off grade of 0.6g/t was selected for the Admiral Group Reserves based on these calculations.

### **Tenure**

All tenements are 100%-owned by one of Genesis Minerals' wholly-owned subsidiaries. All Ore Reserve Estimates, and proposed mining activities are on granted mining leases that are in good standing.

### **Environmental Permitting and Approvals**

All environmental studies have been completed for the Admiral Group Project and regulatory approvals and permits have been approved to continue mining.

### **Infrastructure**

The Admiral Group deposit is located approximately 35km south-east of the Leonora township and is also within driving distance of Kalgoorlie, a major regional hub. Access to the site is via sealed public highways and public and private unsealed roads. The site workforce will be primarily fly-in, fly-out (FIFO) from Perth via the public Leonora airstrip. The workforce will utilise existing Genesis accommodation facilities available at the Leonora township.

The Project will utilise the existing offices, workshops, power, reverse osmosis, and wastewater treatment infrastructure setup in 2023 for mining at the Admiral pit. The Project will also rely on the nearby Ulysses underground mine infrastructure where appropriate. Ore will be hauled using road trains to the existing Gwalia processing plant via sealed public roads, and on occasion, to the Laverton processing plant.

### **Costs**

Load and haul mining costs are built up from first principles by Genesis Mining Services based upon life of asset ownership costs and operating costs. Drill and blast and ore haulage costs are derived directly from tendered prices.

Accommodation is based on current operating costs of the Genesis owned accommodation facilities in Leonora. Flights are based on current chartered rates incurred by Genesis Minerals through the Leonora airport.

Processing, general, and administration costs are based on actual operating costs incurred at both the Gwalia and Laverton operations.

West Australian State Government royalty of 2.5% and third-party royalties of 1% for Admiral were included.

## Economic Outcomes

The Admiral Ore Reserve Estimate is based on a Feasibility level of accuracy with inputs from mining, processing, transportation, sustaining capital and contingencies scheduled and costed to generate the Ore Reserve cost model.

Load and haul mining costs are built up from first principles by Genesis Mining Services based upon life of asset ownership costs and operating costs. Drill and blast costs are derived directly from contracted prices. Road haulage costs are from budget rates supplied by a reputable goldfields haulage contractor. Site capital costs are sourced from tendered pricing for infrastructure. Processing, and general and administration costs are sourced from the current operating costs at the Gwalia Mill and the most recent operating costs for Laverton Mill.

The Ore Reserve returns an economic outcome based on the assumed commodity price and cost estimation, and the Competent Person is satisfied that the project economics that make up the Ore Reserve are suitable based on the mine design, modifying factors, assumptions, and environment.

Sensitivity analysis has indicated that the project drivers are gold price, mining and metallurgical recovery followed by operating expenditure.

## HUB

### RESOURCES & RESERVES SUMMARY

Genesis reports a Mineral Resource Estimate of **0.98Mt at 4.0g/t for 120koz** and Ore Reserve Estimate of **0.34Mt at 2.4g/t for 26koz** for Hub.

Key changes to the previously reported Mineral Resource and Ore Reserve:

- ▶ Updated cost driver based on reconciled actuals and budgeted pricing; and
- ▶ Mining depletion of 33koz.

### HUB MINERAL RESOURCES

#### Geology and Geological Interpretation

The Hub deposit is defined as a meso-thermal, lode gold deposit within the Mertondale Shear Zone, a splay fault zone off the regional Keith–Kilkenny Shear Zone. Mineralisation is hosted largely within Archaean-aged mafic schist and volcano-sediment packages (including chert, black shale, graphitic in part) and intermediate mafic rocks. A mylonitic fabric is observable in the lithologies. Gold mineralisation generally occurs in northerly striking, sub-vertical to steep dipping zones associated with silica-sulphide-mica alteration and veining.

At Hub, mineralisation is hosted in a narrow (~ 4m wide) vertical to steep west dipping lode. Several minor subsidiary hanging and footwall lodes are present. The main lode has been cut by late dolerite and lamprophyre dykes which offset and disrupt the mineralisation in places. The depth of complete oxidation varies from between 50m and 100m below surface which is underlain by a transitional horizon typically 25m thick.

#### Drilling Techniques

The Hub Mineral Resource Estimate has principally been defined through a combination of diamond and reverse circulation (RC) drilling. RAB and air core (AC) holes have been completed in the resource area but have been excluded from both the geological interpretation and the MRE.

Diamond holes typically used NQ (47.6mm) and HQ (63.5mm) sized core. Recovery is recorded by the drillers on core blocks and compared to the measurements of the core by the geologist. Recovery is generally very high (>95%) with no significant sample recovery problems typically recorded. Core is oriented using orientation tools to facilitate structural measurements and cut along a plane passing through the basal orientation mark using a diamond saw.

RC holes used mainly 5½” reverse circulation face sampling hammers with samples typically taken at one metre intervals through a cone splitter. Most samples were dry, but where wet samples were encountered, they were allowed to dry before being split by company personnel.

### **Sampling and sub-sampling techniques**

Diamond core samples were cut in half longitudinally, with intervals from 0.3 to 1.3m in length but were predominantly aligned to 1m intervals or with sample boundaries which respected geological contacts. RC drilling samples were collected in 1m downhole intervals by passing through a cyclone, a collection box and then dropping through a cone splitter. All RC sub-samples were collected over one metre downhole intervals and had an averaged mass of 3-4kg.

### **Sample Analysis Method**

Current sample preparation and assay procedures employed by GMD are considered to follow industry standard practice. All assay determinations are conducted by internationally recognised laboratories. The primary laboratory, BV, meets ISO 9001:2000. Samples are oven dried to remove moisture. All samples are then processed through a jaw crusher to achieve 90% passing < 3mm. The crushed sample is then pulverised for 4 minutes in an LM5 pulveriser for a product of 90% passing < 75µm. Approximately 250 - 300g of the pulp is retained and a 40g charge weight for fire assay is extracted from the pulp packet. Samples are tested for sulphides and flux-adjusted, flux is added at a ratio of 1:4. Samples are fired, hammered and cupelled. Prills are placed in tubes, dissolved on hotplates and analysed using AA finish with over range dilutions.

### **Estimation Methodology**

All domains were estimated using ordinary kriging for grade estimation from a resource dataset of RC and Diamond drilling only. Samples have been flagged by estimation domain wireframes, assigned a unique domain identifier, and composited to 1m. Composites have been analysed for grade outliers and topcut as appropriate to minimise the Coefficient of Variation (CV). Variograms for well supported domains were created to analyse nugget values and the spatial continuity of the data and act as inputs to the OK estimations. All estimation parameters have been derived from Kriging Neighbourhood Analysis (KNA).

The block model used in the estimation has a parent block size of 5x5x5m grade estimation with nested search passes employed informed by variogram ranges.

The models have been depleted for historical mining where appropriate and density has been assigned by weathering profile, rock type and on a lode-by-lode basis (where applicable). Estimated grades have been validated both visually and statistically to ensure conformance to input sample data.

### **Cut-off Grades**

The in situ Mineral Resources have been reported within an optimised pit shell at a 0.50g/t Au cut-off based on Measured, Indicated and Inferred Mineral resources. The Underground Mineral Resource has been reported within mining shape optimiser (MSO) underground shells generated at 2.5g/t cut-off. No assumptions have been made for mining dilution.

### **Resource Classification**

The Hub Mineral Resource is classified as Measured, Indicated, and Inferred using the guidelines of the JORC Code (2012). The categories are assigned based on a combination of physical and estimation quality metrics including mining exposure, drill spacing, kriging metrics, grade and geological continuity. Resource categories are manually assigned to individual lodes via digitised string to the RESCAT attribute. Mineralisation has been categorised as Measured only if it has been exposed by mining or has had grade control drilling to a spacing of 12mx6m. Indicated material is assigned if drill spacing is supported by up to 40mx40m, established grade and geological continuity from drilling and/or historical pit mapping. Inferred material is drill spacing supported by 40mx40m to ~80x80m with limited geological continuity

## Mining Assumptions

Hub open pit Mineral Resource has been reported within reasonable prospects for eventual economic extraction (RPEEE) shell for Indicated and Inferred material at a 0.5g/t cut-off. The underground Mineral Resource has been reported as Indicated and Inferred material only within MSO solids beneath the RPEEE shell.

## Metallurgical Assumptions

Metallurgical testwork carried out by independent consultancies has indicated that there is moderate to high gravity recovery, with total cyanide soluble recoveries reporting between 90-95%.

## Other Modifying Factors

No modifying factors are applied to the Hub Mineral Resource.

## HUB ORE RESERVES

The Hub Ore Reserves have been estimated on a A\$2,800/oz gold price assumption. The Ore Reserve includes only probable classifications. The economically mineable component of the Indicated Mineral Resource has been classified as a Probable Ore Reserve. Updates to the Hub open pit Reserve include mining depletion and minor pit design changes, mining rates and cost assumption refinements based on additional data collated since the 2025 reserves release.

*Table 17. Hub Pit Ore Reserve*

| Project | Proved      |             |             | Probable    |             |             | Proved +Probable |             |             |
|---------|-------------|-------------|-------------|-------------|-------------|-------------|------------------|-------------|-------------|
|         | Tonnes (kt) | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) | Tonnes (kt)      | Grade (g/t) | Ounce (koz) |

|         | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) |
| Hub OP  | 580                    | 3.4         | 65          | 340                    | 2.4         | 26          | -240        | -1.0        | -39         |

The Ore Reserves includes Probable classification estimated based on the economically mineable component of the Measured and Indicated Mineral Resource. No inferred Mineral Resources are included in the Hub Ore Reserves.

*Figure 14. Hub Reserve Pit Designs*

## Mining Method and Assumptions

The Hub Ore Reserves will be mined using 140t rear dump trucks and a 200t & 100t hydraulic excavator mining fleet, using drill and blast on 10m benches and excavators operating on 2.5m flitches. Haul road widths of 27m for dual access roads and 16m for single access roads were used. Minimum mining width of 20m was used for cutbacks and pit benches with the exceptions of goodbye cuts that will be top loaded.

Mining of the pit will be carried out by Genesis Mining Services Pty Ltd (GMS), Genesis' 'internal mining contractor', under an 'owner-operator' model. Leasing and ownership costs have been allocated across the life of the equipment asset. Operating costs for the fleet have been built up utilising the OEM guidance incorporating the operating strategy under the GMS ownership.

Final pit limits were determined from pit optimisations using Whittle Four-X software with inputs from the diluted resource model, geotechnical parameters, metal prices, metallurgical recoveries, royalties, modifying mining factors and operating costs. Appropriate optimisation shells were selected to suit the operation, from which detailed pit designs and mine schedules were completed.

Ore dilution was modelled by applying a modifying factor to the ore tonnes of the resource model. A modifying factor of 25% was determined based on the geometry and grade distribution of the mineral lodes and the SMU. Similarly, mining recovery was modelled by applying a recovery factor of 95% on contained metal in the resource model above COG.

A detailed Geotechnical assessment of the Hub deposit was carried out by geotechnical consultants Peter O'Bryan and Associates which recommended the wall angles and bench heights based on weathering zones and wall orientation. These recommendations were used as the basis for the pit designs.

## Processing Method & Assumptions

Hub ore is free milling and will primarily be processed through the existing Gwalia processing plant. If opportunities arise or strategy dictates, then some Hub ore may be processed at the Laverton processing plant. The Gwalia processing plant consists of a 1.4Mtpa crushing and grinding circuit followed by a conventional gravity recovery and carbon-in-leach (CIL) circuit. The 3.0Mtpa Laverton process plant was commissioned in late March 2018 and includes a semi-Autogenous Grinding, Ball Milling and Pebble Crushing (SABC) comminution circuit followed by conventional gravity and carbon-in-leach (CIL) process.

A metallurgical test work program was completed on Hub ore using samples from RC drill chips in addition to previous test work by NTM Gold Ltd to determine:

- ▶ physical properties for comminution circuit design;
- ▶ optimal grind size; and
- ▶ gold recovery.

The average processing recovery for the Hub deposit is estimated to be 92%. There are no known occurrences of deleterious elements.

## Cut-Off Grade

The Cut Off Grade was derived from cost estimates developed for the Pre-Feasibility Study as well as reconciled actuals from mining completed to date. The cut-off grade used to define ore is the breakeven grade for variable processing and ore haulage costs and a share of the fixed costs for general and administration (G&A) through the Gwalia and Laverton processing plants. A cut-off grade of 0.6g/t was selected for the hub deposit based on these calculations.

## Tenure

All tenements are 100%-owned by Genesis Minerals Limited's wholly-owned subsidiaries. All ore reserve estimates, and proposed mining activities are on granted mining leases that are in good standing.

## Environmental Permitting and Approvals

All environmental studies have been completed for the Hub pit and regulatory approvals and permits have been approved to continue mining.

## Infrastructure

The Hub deposit is located approximately 50km north-east of the Leonora township and is also within driving distance of Kalgoorlie, a major regional hub. Access to the site is via public and private unsealed roads. The site workforce will be primarily fly-in, fly-out (FIFO) from Perth via the public Leonora airstrip. The workforce will utilise existing Genesis accommodation facilities available at the Leonora township.

The Project will utilise the existing offices, workshops, power, reverse osmosis, and wastewater treatment infrastructure setup in 2024 for Mining at Hub pit. Ore will be hauled using road trains to the existing Gwalia processing plant via sealed and unsealed public roads, and on occasion to the Laverton processing plant.

## Costs

Load and haul mining costs are built up from first principles by Genesis Mining Services based upon life of asset ownership costs and operating costs. Drill and blast costs are derived directly from tendered prices. Surface haulage costs were sourced from quotations received from reputable road haulage contractors that operate in the Goldfields region.

Accommodation is based on current operating costs of the Genesis owned accommodation facilities in Leonora. Flights are based on current chartered rates incurred by Genesis Minerals through the Leonora airport.

Processing, and general and administration costs, are based on actual operating costs incurred at both the Gwalia and Laverton operations.

West Australian State Government royalty of 2.5% were included. No third-party royalties are applicable.

## Economic Outcomes

The Hub Ore Reserve Estimate is based on a Feasibility level of accuracy with inputs from mining, processing, transportation, sustaining capital and contingencies scheduled and costed to generate the Ore Reserve cost model.

Load and haul mining costs are built up from first principles by Genesis Mining Services based upon life of asset ownership costs and operating costs. Drill and blast costs are derived directly from tendered prices. Road haulage costs are from budget rates supplied by a reputable goldfields haulage contractor. Site capital costs are sourced from tendered pricing for infrastructure. Processing, and general and administrative (G&A) costs are sourced from the current operating costs at the Gwalia Mill and the most recent operating costs for Laverton Mill.

The Hub Ore Reserve returns an economic outcome based on the assumed commodity price and cost estimation, and the Competent Person is satisfied that the project economics that make up the Ore Reserve are suitable based on the mine design, modifying factors, assumptions, and environment.

Sensitivity analysis has indicated that the project drivers are gold price, mining and metallurgical recovery followed by operating expenditure.

## TOWER HILL

### RESOURCES & RESERVES SUMMARY

Genesis Mineral reports a Resource Estimate of **21Mt at 2.5g/t for 1.6Moz** and Ore Reserve Estimate of **17.0Mt at 2.0g/t for 1.1Moz** for Tower Hill.

Key changes to the previously reported Ore Reserve:

- ▶ Updated design and scheduling inputs based on fleet selection criteria; and
- ▶ Cost drivers based on updated milling and haulage scenarios

## **TOWER HILL MINERAL RESOURCES**

### **Geology and Geological Interpretation**

Gross stratigraphy at Tower Hill from west to east is represented by a granitic footwall (FW), followed by a strongly deformed and foliated ultramafic unit, through to a mafic hanging wall (HW). Gold mineralisation is hosted in a moderately (35-50°) east dipping quartz vein package that sits locally between the granitic FW and the ultramafic HW. Quartz veins trend north-north-west and extend over a 1km strike. The quartz veins range from 1m to nearly 50m in width at the widest point. Gold distribution within quartz veins is ambiguous and it is difficult to confidently distinguish between mineralised and unmineralised veins. In general, veins within the mineralised sequence have internal laminations, fractures, and sulphides.

The hydrothermal system at Tower Hill comprises two dominant alteration facies: the potassic alteration zone and the regional carbonation zone. The potassic alteration zone lies adjacent to, and encompasses, the granite-ultramafic contact. Immediately east of the potassic zone is the regional carbonation zone which is characterised by ultramafic comprising a talc-chlorite-carbonate assemblage. All auriferous veins lie within the potassic alteration zone.

### **Drilling Techniques**

The Tower Hill Mineral Resource has principally been defined by a combination of diamond and reverse circulation (RC) drilling. RAB and air core (AC) holes have been completed in the resource area but have been excluded from both the geological interpretation and the MRE.

Diamond holes typically used NQ (47.6mm) and HQ (63.5mm) sized core. Recovery is recorded by the drillers on core blocks and compared to the measurements of the core by the geologist. Recovery is generally very high (>95%) with no significant sample recovery problems typically recorded. Core is oriented using orientation tools to facilitate structural measurements and cut along a plane passing through the basal orientation mark using a diamond saw.

RC holes used mainly 5½" reverse circulation face sampling hammers with samples typically taken at one metre intervals through a cone splitter. Most samples were dry, but where wet samples were encountered, they were allowed to dry before being split by company personnel.

### **Sampling and sub-sampling techniques**

Diamond core samples were cut in half longitudinally, with intervals from 0.3 to 1.3m in length but were predominantly aligned to 1m intervals or with sample boundaries which respected geological contacts. RC drilling samples were collected in 1m downhole intervals by passing through a cyclone, a collection box and then dropping through a cone splitter. All RC sub-samples were collected over one metre downhole intervals and had an averaged mass of 3-4kg.

### **Sample Analysis Method**

Current sample preparation and assay procedures employed by Genesis are considered to follow industry standard practice. All assay determinations are conducted by internationally recognised laboratories. The primary laboratory, SGS, meets ISO 9001:2000. Samples are oven dried until a constant mass is achieved. All samples are then processed through a jaw crusher to 90% passing < 3mm. The crushed sample is then pulverised for 4 minutes in an LM5 pulveriser for a product of 90% passing < 75µm. Approximately 250 - 300g of the pulp is retained and a 40g charge weight for fire assay is extracted from the pulp packet. Samples are tested for sulphides and flux-adjusted, flux is added at a ratio of 1:4. Samples are fired, hammered and cupelled. Prills are placed in tubes, dissolved on hotplates and analysed using AA finish with over range dilutions.

## Estimation Methodology

All domains were estimated using ordinary kriging for grade estimation from a resource dataset of RC and Diamond drilling only. Samples have been flagged by estimation domain wireframes, assigned a unique domain identifier, and composited to 1m. Composites have been analysed for grade outliers and topcut as appropriate to minimise the Coefficient of Variation (CV). Variograms for well supported domains were created to analyse nugget values and the spatial continuity of the data and act as inputs to the OK estimations. All estimation parameters have been derived from Kriging Neighbourhood Analysis (KNA). Where lodes exhibit bi/multi-model grade populations, categorical indicator kriging (CIK) has been utilised to generate sub-domains within lodes prior to grade estimation using ordinary kriging.

The block model used in the CIK estimation has blocks set at 1x2x1m to ensure sub-domain complexity is maintained then optimised and re-blocked to the parent block size of 5mx10mx5m for parent cell size grade estimation with a nested search passes employed informed by variogram ranges.

The models have been depleted for historical mining where appropriate and bulk density has been assigned by weathering profile and on a lode-by-lode basis. Estimated grades have been validated both visually and statistically to ensure conformance to input sample data.

## Cut-off Grades

The in situ resources have been reported within an optimised pit shell at a 0.40g/t Au cut-off based on Measured, Indicated and Inferred Mineral resources. The Underground Mining Resource has been reported within MSO underground shells generated at 2.5g/t cut-off. No assumptions have been made for mining dilution.

## Resource Classification

The Tower Hill Mineral Resource is classified as Measured, Indicated or Inferred using the guidelines of the JORC Code (2012). The categories are assigned based on a combination of physical and estimation quality metrics including mining exposure, drill spacing, kriging metrics, grade and geological continuity. Resource categories are manually assigned to individual lodes via digitised string to the RESCAT attribute. Mineralisation has been categorised as Measured only if it has been exposed by mining. Indicated material is assigned if drill spacing is supported by up to 40mx40m, established grade and geological continuity from drilling and/or historical pit mapping. Inferred material is drill spacing supported by 40mx40m to ~80mx80m with limited geological continuity.

## Mining Assumptions

Tower Hill open pit Mineral Resource has been reported within a pit optimisation shell that allows the test of reasonable prospects of eventual economic extraction (RPEEE) for in situ Indicated and Inferred Mineral Resource material at a 0.4g/t cut-off. The underground resource has been reported as Indicated and Inferred material only within MSO solids beneath the RPEEE shell.

## Metallurgical Assumptions

Metallurgical test work carried out by independent consultancies has indicated that there is moderate to high gravity recovery, with total cyanide soluble recoveries reporting between 91-93%.

## Other Modifying Factors

No modifying factors are applied to the Mineral Resource.

## TOWER HILL ORE RESERVES

The Tower Hill Ore Reserves are estimated based on a recent Pre-Feasibility Study (PFS) undertaken by Genesis Minerals. The Ore Reserves have been estimated on A\$2,800/oz gold price assumption. Updated Mineral Resource

Estimates underpins the comprehensive application of modifying factors to develop practically achievable and economically minable Ore Reserves Estimation for Tower Hill.

*Table 19: Tower Hill Ore Reserve*

| Project | Proved      |             |             | Probable    |             |             | Proved + Probable |             |             |

| Hub OP  | -           | -           | -           | 17,000      | 2.0         | 1,100       | 17,000            | 2.0         | 1,100       |

*Table 20. Tower Hill Comparison to Previous Ore Reserve*

| Project | Reserve at 31 Dec 2024 |             |             | Reserve at 31 Dec 2025 |             |             | Variance    |             |             |
|---------|------------------------|-------------|-------------|------------------------|-------------|-------------|-------------|-------------|-------------|
|         | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) |
| Hub OP  | 15,000                 | 2.0         | 1,000       | 17,000                 | 2.0         | 1,100       | 2,000       | -           | 100         |

The Ore Reserves includes Probable classification estimated based on the economically mineable component of the Measured and Indicated Mineral Resource. No inferred Mineral Resources are included in the Ore Reserves.

*Figure 15. Tower Hill Open Pit LOM*

## Mining Method and Assumptions

The Tower Hill Ore Reserves are based on mining of a Life of Mine Reserve open pit through multiple stages. Mine planning assumptions are updated for the PFS and validated through current operational performance.

- ▶ Tower Hill Life of Mine pit limit was determined from pit optimisations using Whittle Four-X software. The optimisation process takes multiple inputs such as diluted resource model, geotechnical parameters and metal prices, metallurgical recoveries, royalties, modifying mining factors and operating costs to delineate a series of nested pit shells using a range of revenue factors. An appropriate pit shell was then selected and utilised as the guideline for the detailed Life of Mine pit design and mine scheduling work.
- ▶ Tower Hill will utilise a conventional open pit mining method, carried out using 240t rear dump trucks loaded by 300t to 600t capacity hydraulic excavators. Drill and blast will be carried out on 10m benches and excavators will be operating on three sets of 4m flitches, that include blast heave. The mining method applied is considered to be practical and appropriate for the scale and geometry of the Tower Hill deposit. The Life of Mine schedule was developed using practically achievable productivity rates and a mining sequence to deliver consistent ore supply to the processing plant whilst moderating the pre-strip ratio through pit staging.

- ▶ The construction sequence and development planning of noise bunds and waste dumps were prepared in accordance with noise and height assessment recommendations from specialist noise consultants. A Construction Noise Management Plan (CNMP) will cover the first 12 months of mining to facilitate the construction of noise bunds and a portion of the waste rock landform. As an extra level of conservatism in the mine schedule, it has been assumed that, despite the assumption of a CNMP being in place, mining on night shift will not be permissible 20% of the time due to self-imposed restrictions.
- ▶ The waste rock landform design has been informed by the following: proximity to the Leonora airport and the associated flight path approaches and take-off corridors (Obstacle Limitation Surfaces (OLS) & pans-ops surfaces), heritage requests in consultation with the Darlot Group with regard to the height of the neighbouring Mt Leonora, the adjacent Wilsons Creek and associated sheet flow (rock armouring), the Heritage precinct, and noise compliance requirements.
- ▶ A detailed Geotechnical assessment of the Tower Hill deposit was carried out by AMC consultants during the PFS. The study was based on two weathering zones, with inter ramp angle ranging from 33° (50° batter angles, 7m berms and 10m batter heights) to 55° (70° batter angles, 7m berms and 20m batter heights), which represents an overall slope of approximately 39° to 48° after inclusion of the designed ramp system.
- ▶ Those portions of the upper benches of the deposit that contain ore will be RC grade controlled prior to the commencement of mining, with subsequent grade control passes occurring at bench intervals and on patterns to be dictated by the mining schedule and lode width and geometry.
- ▶ Historical underground mining of Tower Hill from early in the last century was largely removed by the open pit that was mined out in the 1980s. There is still some evidence of old shafts and workings to the east of the existing pit within the footprint of the Genesis reserve pit design. Old historical plans suggest that several of these shafts are angled back westwards towards and possibly beneath the existing pit and are likely to be encountered when mining the reserve pit. Genesis will draw on the experience of several of its technical staff with extensive knowledge of mining through voids to plan a program of probe drilling and draw up a set of procedures for safe working around voids.
- ▶ Drill and blast practices at Tower Hill will be developed in line with recommendations from specialist consultants due to the proximity of the Leonora townsite. Consideration will be given to vibration, dust generation, air blast pressure, noise, and flyrock when scheduling and designing blasts in the Tower Hill pit. The determination of an appropriate blast exclusion zone limit and the requirements for closure of the adjacent Goldfields Highway for blasting will be developed in close consultation with blasting consultants. The initial stage(s) of the pit are located furthest away from both the townsite and from the Highway, allowing ample time for refinement and iterative learnings from the initial pit blasts, based upon the behaviour of different material types in the pit.
- ▶ Ore dilution and loss (mining recovery) was modelled through the Stope optimiser (SO) software to determine the practically minable diluted ore blocks through the selected mining method and excavator class. The SO process used a cut-off grade of 0.5g/t and considers the mineralisation dip/direction, minimum mining width, height and length specification of the ore block to determine the application of additional dilution skins around the mineralisation boundaries to accommodate potential dilution and ore loss that occurs due to mining practicalities. The resultant diluted ore blocks are then scheduled for mining through an industry leading software package with bench turnover constraints applied.
- ▶ 30m haul road widths for dual lane access ramp and 16m for single access ramp are used in the Tower Hill pit design. The Life of Mine pit stage options were designed with a bench minimum mining width of 40m and a goodbye cut minimum mining width of 30m at the bottom of the pit.
- ▶ Inferred Mineral Resources were excluded from pit optimisations for the Ore Reserve estimation and treated as waste material.

## Processing Method & Assumptions

The Tower Hill ore is free milling and will primarily be processed through the existing the new Tower Hill Process Plant. If opportunities arise or strategy dictates, then some Tower Hill ore may be processed at the Laverton or Gwalia processing plant. The 3.5-4.0Mtpa Toer Hill Process Plant will consist of single stage crushing, Semi-Autogenous Grinding, Ball

Milling and Pebble Crushing (SABC) comminution circuit followed by conventional gravity and carbon-in-leach (CIL) process.

The technology associated with the processing of Gwalia ore is currently in operation and is based on industry standard practices.

A PFS level metallurgical testwork program was completed in Perth by Bureau Veritas Pty Ltd (BV) and managed by Mintrex Pty Ltd. There were 9 variability samples, 1 master composite sample and 3 low-grade samples were tested for the following criteria;

- ▶ Physical properties for comminution circuit design;
- ▶ Conditions for optimal leaching; and
- ▶ Gold recovery.

The proposed Tower Hill Gold Plant Recovery Model is based on metallurgical testwork and categorised into two head grade zones for a grind size of 110µm. The table below shows the predicted recovery model for head grades of 1.25g/t and 1.5g/t.

*Table 21: Predicted Recovery Model*

| Gold Head Grade g/t | Predicted Au Recovery %    |
|---------------------|----------------------------|
| ≤1.25               | $0.2404 \cdot HG + 5834$   |
| ≥1.50               | $0.0097 \cdot HG + 0.8930$ |

There are no known deleterious elements identified for the mineralogical/metallurgical assessments carried out during the pre-feasibility test work.

No bulk sample test or pilot scale testwork has been performed. However, between 2011 to 2013 low grade stockpile material from Tower Hill was processed through the Gwalia plant. Ore from the Tower Hill deposit will be blended with other ore sources at the Laverton processing plant. No minerals are defined by a specification.

### **Cut-Off Grade**

The cut-off grade of 0.50g/t Au is defined as the breakeven grade and estimated using the reserve gold price assumption of A\$2,800/oz. The cut-off grade estimation uses all operating costs associated with processing, ore transportation, royalty payments, and costs for general and administration (G&A) that occurs through the Laverton processing operation.

### **Tenure**

The Tower Hill deposit is located on granted mining leases 100%-owned by subsidiaries of Genesis Minerals Limited and are all in good standing. The Darlot Group are the determined Native Title holders over the project area. Genesis has established positive engagement with all stakeholders impacted by the development of the Tower Hill project.

### **Environmental Permitting and Approvals**

Tower Hill project sits on a granted mining lease and the area has previously been significantly impacted by mining. A dewatering licence to dewater the existing Tower Hill pit to the Harbour Lights pit has been granted and flora and fauna studies for the region are completed.

Genesis has received early advice from the Environmental Protection Authority (EPA) that the EPA determined to not assess the proposal on the basis that the matters could be largely managed through secondary approvals i.e. Tower Hill can be managed via the standard WA mining approval process.

All key relevant stakeholders have been engaged and good relationships maintained in relation to the development of the Tower Hill project. There are no notable concerns raised to date. Genesis is currently working with the Darlot Group, who are the determined Native Title holders over the project area and has established positive engagement and discussions since acquiring the asset. A mining agreement has been entered into with the Darlot Group.

Study work has been completed for Tower Hill rock samples for the characterisation of waste rock and waste dump design. Waste rock has been classified as non-acid forming (NAF) and therefore no specific encapsulation is required for any rock material within the waste dump.

## **Infrastructure**

The Tower Hill project is located in proximity to Leonora township and within driving distance of Kalgoorlie, a major regional hub. Access to the site is via the sealed Leonora-Kalgoorlie highway.

The project will require establishment of new offices, workshops, surface mining service facilities, dewatering pipeline to Harbour Lights, wash bay, site power, reverse osmosis plant, and a wastewater treatment plant. Some existing infrastructure adjacent to the Tower Hill pit including rail and an underground gas pipeline will require relocation or removal to facilitate mining and waste rock landform construction.

The site workforce will be a combination of drive-in, drive-out from nearby townships and fly-in, fly-out (FIFO) from Perth via the public Leonora airstrip and accommodated within existing Genesis-owned Gwalia village facilities. The Tower Hill project will also rely on the nearby Gwalia underground mine infrastructure where appropriate.

Tower Hill ore will be treated at the new Tower Hill processing plant, and on occasion, at the Laverton processing plant, and transported via road trains using combination of sealed public roads and dedicated gravel roads. The new Tower Hill processing plant will be powered through the expansion (21MW-33MW) of the current Gwalia gas-fired power station, and supported by current infrastructure including a bore field and tailings storage facility; a 400-person capacity accommodation village; administration offices; workshops; and reverse osmosis and wastewater treatment plants.

## **Costs**

The PFS study for Tower Hill includes a comprehensive cost estimate based upon current operational costs, quotations, study work by consultants, engagement with stakeholder groups and mining costs from Genesis Mining Services.

Mining costs for load and haul are estimated based on mining equipment requirements through a detailed mine planning and scheduling process and validated by in-house mining service providers (Genesis Mining Services). The drill and blast costs are estimated using costs provided by an existing contract service provider at Admiral open pit.

Processing costs have been generated from the combination of recent costs since the recommissioning of the Laverton processing plant in October 2024, the plant's past operating performance, as well as studies conducted by external consultants. The plant consumables and labour costs have been validated against current operational costs at the Gwalia processing plant. Test work does not indicate the presence of any deleterious elements.

All costs and revenues are in Australian dollars, and no exchange rates were used.

Transportation charges for ore from Tower Hill to the Laverton processing plant are based upon current contract rates supplied by Genesis' contract haulage company.

West Australian State Government royalty of 2.5% and third-party royalties of 1.92% were included based on statutory or agreed rates as appropriate.

## **Economic Outcomes**

Tower Hill Ore Reserves deliver a technically achievable and economically viable operation based on the financial assessment performed over the Life of Mine operation. Ounce production and gold recovery estimates for revenue calculations were based on detailed mine designs, mine schedules, mining factors and cost estimates for mining and processing.

The Ore Reserve estimate is based on a pre-feasibility level of accuracy with up-to-date inputs from geology, mining, processing, transportation, royalty payment, sustaining capital to generate the Tower Hill Ore Reserve cost model. The Tower Hill Ore Reserve is technically achievable and economically viable based on the assumed gold price of A\$2,800 per ounce and cost estimations. No other revenue factors and sources were used.

Tower Hill project economics that make up the Ore Reserve Estimate are practical and suitable based on the mine design, modifying factors, planning assumptions, and for social and environment factors.

NPV sensitivity tested for the critical driving factors, and they demonstrate a significant positive outcome for the Tower Hill Ore Reserve. There are reasonable prospects to anticipate that relevant legal, environmental, and social approvals to operate Tower Hill project will be granted within the projected timeframe.

## JUPITER

### RESOURCES & RESERVES SUMMARY

Genesis Minerals reports a Mineral Resource Estimate for Jupiter of **22Mt at 1.0g/t for 0.74Moz** with a reduction in the Ore Reserve Estimate to **6.8Mt at 0.9g/t for 0.2Moz**.

Key changes to the previously reported Ore Reserve:

- ▶ Reduction in MRE; and
- ▶ Mining depletion of 6koz.

### JUPITER MINERAL RESOURCES

#### Geology and Geological Interpretation

The Jupiter Gold Deposit includes the Doublejay, Heffernans, and Ganymede prospects within the Laverton district, Western Australia.

Jupiter is an Archean syenite related, lode gold style deposit. The geology of the Jupiter deposit comprises undifferentiated basalt and pillow basalts intruded by syenite pipes, syenite dykes, and felsic, intermediate, and lesser mafic porphyries.

The Jupiter deposit is interpreted to comprise structurally controlled mesothermal gold mineralisation related to syenite intrusions within altered basalt. Most mineralisation is associated with large, shallow, east-dipping shears, most significantly developed where these shears crosscut syenite intrusions or the altered pillow basalt proximal to the syenite intrusions.

A deposit-scale structure zone known as the Cornwall Shear Zone (CSZ) extends the entire length of the Jupiter deposit, which typically displays distinctly elevated mineralisation tenor compared to the surrounding basalt country rock. Lesser tenor mineralisation is noted lying subparallel to the CSZ in a stacked or en echelon sense, particularly above the CSZ.

#### Drilling Techniques

The Jupiter resource has been primarily delineated through a combination of diamond and reverse circulation (RC) drilling. While RAB and air core (AC) holes have been drilled within the resource area, they have been excluded from both the geological interpretation and the Mineral Resource Estimate (MRE).

Diamond holes typically used NQ (47.6mm) and HQ (63.5mm) sized core. Recovery is recorded by the drillers on core blocks and compared to the measurements of the core by the geologist. Recovery is generally very high (>95%) with no significant sample recovery problems typically recorded. Core is oriented using orientation tools to facilitate structural measurements and cut along a plane passing through the basal orientation mark using a diamond saw.

RC holes used mainly 5½" reverse circulation face sampling hammers with samples typically taken at one metre intervals through a cone splitter. Most samples were dry, but where wet samples were encountered, they were allowed to dry before being split by company personnel.

### **Sampling and sub-sampling techniques**

Diamond core samples were cut in half longitudinally, with intervals from 0.3 to 1.3m in length but were predominantly aligned to 1m intervals or with sample boundaries which respected geological contacts. RC drilling samples were collected in 1m downhole intervals by passing through a cyclone, a collection box and then dropping through a cone splitter. All RC sub-samples were collected over one metre downhole intervals and had an averaged mass of 3-4kg.

### **Sample Analysis Method**

Sample preparation included oven drying (105°C), crushing (<6mm), pulverising (P90% passing 75µm) and split to obtain a 50-gram catchweight. Analysis for gold only was carried out by Fire Assay fusion technique with AAS finish. Blanks and CRM standards were inserted in each sample batch at a ratio of 1:20. Field duplicates were typically collected at a ratio of 1:25 samples. Laboratory pulp grind and crush checks were typically requested at a ratio of 1:50 or less. Best practice QAQC methods for all drilling operations and the treatment and analysis of samples have been implemented and adhered to.

### **Estimation Methodology**

Gold grades have been estimated using Ordinary Kriging (OK) from a resource dataset of RC and Diamond drilling only. Samples have been flagged by estimation domain wireframes, assigned a unique domain identifier, and composited to 1m. Composites have been analysed for grade outliers and topcut as appropriate to minimise the Coefficient of Variation (CV). Variograms for well supported domains were created to analyse nugget values and the spatial continuity of the data and act as inputs to the OK estimations. All estimation parameters have been derived from Kriging Neighbourhood Analysis (KNA). Parent block sizes have been set at 5x5x5m for Jupiter with a nested search passes employed informed by variogram ranges. The models have been depleted for historical mining where appropriate and bulk density has been assigned by weathering profile. Estimated grades have been validated both visually and statistically to ensure conformance to input sample data.

### **Cut-off Grades**

The MRE has been reported above a lower cut-off of 0.4g/t Au and within a pit optimisation shell that allows the test of reasonable prospects of eventual economic extraction (RPEEE) for in situ material only.

### **Resource Classification**

The Jupiter resource is classified as Measured, Indicated, Inferred, or Potential (Unclassified) using the guidelines of the JORC Code (2012). The categories are assigned based on a combination of physical and estimation quality metrics including mining exposure, drill spacing, kriging metrics, grade and geological continuity. Resource categories are manually assigned to individual lodes via digitised string to the RESCAT attribute. Mineralisation has been categorised as Measured only if it has been exposed by mining. Indicated material is assigned if drill spacing is supported by up to 20mx30m, established grade and geological continuity from drilling and/or historical pit mapping. Inferred material is drill spacing supported by up to 40mx40m with limited geological continuity. All other mineralisation is assigned a Potential resource category.

### **Mining Assumptions**

Dacian Gold Limited mined Jupiter via open pit methods from December 2017 to June 2022. Open pit mining recommenced with Genesis in 2025 with ore being processed through the Mt Morgans Mill and will continue to do so as per the Genesis 10-year LOM plan.

### Metallurgical Assumptions

Ore mined at Jupiter is processed at the adjacent Mt Morgans mill, with recoveries of 91% achieved.

### Other Modifying Factors

No modifying factors are applied to the Mineral Resource.

### JUPITER ORE RESERVES

The Jupiter Ore Reserves have been estimated on a A\$2,800/oz gold price assumption. The updated Mineral Resource estimation underpins the comprehensive application of modifying factors to develop a practically achievable and economically minable Ore Reserves Estimation for Jupiter.

*Table 22: Jupiter Ore Reserve*

| Project    | Proved      |             |             | Probable    |             |             | Proved +Probable |             |             |

The Ore Reserves includes a Probable classification estimate based on the economically mineable component of the Measured and Indicated Mineral Resource. No inferred Mineral Resources are included in the Ore Reserves.

The key material change in the modifying factors and assumptions for the 2025 Ore Reserves is listed below;

- Mining depletion 6koz.

*Figure 16. Jupiter Ore Reserve Layout*

## Mining Method and Assumptions

The Jupiter pits were historically mined (December 2017 to June 2022) via mechanised open pit methods utilising conventional mining equipment. The updated mining estimate is based on the same approach and the equipment selected remains appropriate in this MRE.

Ore dilution was modelled using minable shape optimisation (MSO) software to generate minable ore block designs. This accounts for planned ore loss and dilution. A skin was then applied to these ore blocks to account for unplanned ore loss and dilution.

Ore Reserve estimate is based on utilising conventional open pit mining methods with hydraulic excavator and dump trucks along with drill and blast activities to support the operational performance and efficiency. The 200t class excavator has been assumed for mining, loading 140t rear dump trucks which determine productivity rates and mining dilution and ore loss factors. Minimum mining bench widths of 25m have been assumed based on selected mining equipment for cutbacks and pit benches. Haul roads width of 31m for dual access roads and 18m for single access roads were used.

Mining of the pit will be carried out by Genesis Mining Services Pty Ltd (GMS) an internal mining contractor utilising a newly acquired mining fleet under an 'owner-operator' model. Leasing and ownership costs have been allocated across the life of the equipment asset. Operating cost for the fleet has been built up utilising the OEM guidance incorporating strategy under the GMS ownership. Productivity rate estimation is based on first principles using selected equipment specifications and validated against industry benchmark and past operational performance to determine achievable productivity.

Regular geotechnical inspections by an independent geotechnical engineer were historically carried out on the Jupiter open pits. Their most recent recommendations have been included as part of the pit design update. Pit designs were validated against optimised pit shells as part of the initial design process for the Ore Reserve Estimate.

No Inferred Mineral Resources have been included in the Ore Reserve Estimate. Inferred Mineral Resources were treated as waste and assigned no economic value. A detailed pit design and associated mine schedule were completed and a financial analysis undertaken to confirm that the design and associated mining schedule provided a positive economic return.

## Processing Method & Assumptions

The Jupiter ore is free milling mineralised material and will be processed through the existing 3.0Mtpa capacity at the Laverton processing plant. The Laverton processing plant was commissioned in late March 2018 and includes a Semi-Autogenous Grinding, Ball Milling and Pebble Crushing (SABC) comminution circuit followed by conventional gravity and carbon-in-leach (CIL) process.

The Laverton process plant was commissioned in late March 2018 and processed a total of 14.2Mt (dry) prior to the plant being placed in care and maintenance in March 2023. The average gold recovery over this period was 92.3% for a blended feed from the Jupiter open pits, Westralia underground as well as the Mt Marven open pit. A recovery of 92% was used for the economic evaluation of the Jupiter open pits.

The Jupiter Recovery Model is based on actual reconciled monthly processing data from the Laverton processing plant.

The  $\leq 0.7\text{g/t}$  head grade recovery assumption was determined from October 2022 and December 2022 monthly reconciled data where a total of 0.5Mt (dry) was processed. In this dataset Jupiter Low Grade Stockpiles was processed at a Mill Feed blend of 90%.

The  $\geq 0.8$  to  $\leq 1.4\text{g/t}$  head grade and the  $> 1.4\text{g/t}$  head grade recovery assumptions were determined from 28 months of reconciled data. In this dataset Jupiter ore was processed at a Mill Feed blend of  $> 70\%$  and the total ore processed was 6.8Mt (dry) accounting for 48% of the total ore processed through Laverton.

No deleterious elements were identified from the mineralogical/metallurgical assessments carried out during the 2016 DFS and evidence of such has not been observed during ore processing operations from plant commissioning in March 2018 to December 2022.

In addition to processing ore from the Heffernans and Doublejay deposits as a component of the mill feed blend from March 2018, previous owners have also treated approximately 10Mt of ore through the historic Laverton treatment plant during the 1990s. This included ore mined from the historic Joanne and Jenny pits (now subject to a cutback as the Doublejay pit). The average recovery during the 10-year period was 91.4% for 740,000 ounces produced.

### **Cut-Off Grade**

A break-even cut-off grade was determined for the Jupiter Ore Reserve by considering:

- ▶ Gold price;
- ▶ Achieved gold recovery from ore processing;
- ▶ Mining costs comprised of updated mining contractor costs;
- ▶ Current ore processing costs; and
- ▶ Royalties.

The calculated breakeven cut-off grade at a gold price of A\$2,800 AUD/oz equates to 0.4g/t.

### **Tenure**

The Jupiter deposit is located on tenement M39/236 and is 100%-owned by a wholly-owned subsidiary of Genesis Minerals Limited. The Jupiter Ore Reserve Estimate, and the proposed mining activities are on granted mining leases that are in good standing.

### **Environmental Permitting and Approvals**

All regulatory approvals and permits have been granted for the Jupiter Project for ongoing mining and processing at Laverton processing plant, including mining of the Jupiter Mining Area. This includes approvals for extensions to the tailings storage facility (TSF) and water sourced from a combination of the current pit workings and the licensed Laverton bore field. An addendum to the mining proposal is required to cover the planned extension to the pit. At this stage there are no known reasons to believe that this additional approval will not be approved on time and prior to mining commencing.

Waste rock characterisation was completed on drill samples as a component of the 2016 DFS. All Jupiter waste rocks were characterised as non-acid forming (NAF) apart from highly localised portions of basalt and to a lesser extent, intermediate quartz porphyry. This material accounts for less than 6% of all waste rock mined from the Jupiter pits.

There are no known heritage or environmental impediments over the leases where significant results were received. The tenure is secure at the time of reporting. No known impediments exist to operate in the area.

Genesis has security of tenure for all current exploration licences and the mining lease that covers its future Ore Reserves. There are no material issues relating to native title or heritage, historical sites, wilderness or national parks, or environmental settings.

### **Infrastructure**

The Jupiter Project is in the immediate vicinity of the Laverton and Leonora townships and is within driving distance of Kalgoorlie, a major regional hub. Access to the site is via sealed public highways and public and private unsealed roads.

The site workforce is primarily fly-in, fly-out (FIFO) from Perth via the public Leonora airstrip.

The Laverton site is well established with a modern processing plant, associated 16.5MW gas fired power station, bore field and tailings storage facility; a 400-person capacity accommodation village; administration offices; workshops; and reverse osmosis and wastewater treatment plants.

## Costs

Jupiter Ore Reserves established a comprehensive capital cost estimation based on the progress made with the various stakeholder's engagement, quotations and cost estimations from external consultants, current operating open pit sites and Genesis Mining Services.

Mining costs for load and haul are estimated based on mining equipment requirements through a detailed mine planning and scheduling process and validated by in-house mining service providers (Genesis Mining Services). The drill and blast cost is estimated using costs provided by an existing contract service provider at the Admiral open pit.

Processing costs have been generated from the combination of recent costs since recommissioning of the Laverton processing plant in October 2024, past operating performance, as well as studies conducted by external consultants. The Jupiter open pit ore tonnes to be processed at the mill only have the variable processing, and general and administration (G&A) costs attributed to them. Accommodation is based on the current camp infrastructure. Flights are based on current chartered rates incurred by Genesis Minerals through Leonora airport.

All revenue and cost calculations are based on Australian Dollars; hence application of an exchange rate has not been required. In addition, a 2.5% Western Australian State Government royalty has been allowed for and the Competent Person is satisfied that the project economics that make up the Ore Reserve are suitable based on the mine design, modifying factors, assumptions and the environment.

## Economic Outcomes

Jupiter Ore Reserves delivers the technically achievable and economically viable operation based on the financial assessment performed over the Life of Mine operation. Ounces production and gold recovery estimates for revenue calculations were based on detailed mine designs, mine schedules, mining factors and cost estimates for mining and processing.

The Jupiter Ore Reserve Estimate is based on a pre-feasibility level of accuracy with up-to-date inputs from geology, mining, processing, transportation, royalty payment and sustaining capital to generate the Jupiter Ore Reserve cost model. The Jupiter Ore Reserve is technically achievable and economically viable based on the assumed gold price of A\$2,800 per ounce and cost estimations. No other revenue factors and sources were used.

The Jupiter Project economics that make up the Ore Reserve Estimate is practical and suitable based on the mine design, modifying factors, planning assumptions, and for social and environment factors.

The Ore Reserve returns a positive economic outcome based on the assumed commodity price and cost estimations. As with all gold projects, the primary sensitivity is the gold price.

## CARDINIA WEST (BRUNO-LEWIS & KYTE)

### RESOURCES & RESERVES SUMMARY

Genesis Mineral Resource Estimate for Bruno-Lewis and Kyte of **13Mt at 1.0g/t for 0.44Moz** and Ore Reserve Estimate of **9.2Mt at 1.0g/t for 0.28Moz**.

Key changes to the previously reported Ore Reserve:

- ▶ Additional drilling, geological interpretation review and re-estimation using the Categorical Indicator Kriging (CIK) technique prior to grade estimation with Ordinary Kriging (OK); and
- ▶ Increase in Indicated Mineral Resource classification material within the immediate vicinity of the previously reported Ore Reserve material

### BRUNO-LEWIS & KYTE MINERAL RESOURCES

#### Geology and Geological Interpretation

Deposit stratigraphy constitutes west dipping parallel belts of mafic (basalts and dolerites) and felsic volcanics, with interbedded shales and siltstones commonly found on the contacts. At the approximate location of the Lewis trial pit, there

is evidence for the stratigraphy offset by faulting, possibly sinistral strike slip movement. The stratigraphy is intruded by several NW striking and NE dipping felsic porphyry units as well as later Proterozoic dolerite dykes. Mineralisation consists of the following types:

- ▶ Potassic Lodes - Moderately NE-dipping, NW-striking primary mineralisation lodes, associated with and sub-parallel to the NE-dipping porphyry intrusions. Characterised by potassic alteration, quartz stockwork veining and disseminated pyrite.
- ▶ Contact Lodes - Moderate to steeply W-dipping, stratigraphy-parallel primary mineralisation lodes. Located on or near the stratigraphic contacts, or within the central interbedded volcanoclastic and sediment unit. Typically, pyrite-rich with limited strike extent. Due to the deeper weathering in the north, and a lack of drilling into fresh rock, the Northern lodes are more poorly defined than the southern lodes.
- ▶ Supergene - Flat lying and situated within the oxide. The supergene domains form cohesive blankets, with a preference for a mafic host. There is a clear spatial relationship between some of the supergene and the NW striking cross-cutting felsic porphyries.

### **Drilling Techniques**

Bruno-Lewis and Kyte mineralisation has primarily been defined by Diamond and Reverse Circulation (RC) drilling. Diamond drilling has been completed at NQ2 (47mm) and HQ3 (64mm) core sizes and oriented to facilitate the acquisition of structural data. RC drilling has typically been completed utilising 140mm downhole face-sampling hammer bits. Downhole survey has been completed using electronic multi-shot survey tools and intermittent gyroscopic surveys. Holes were surveyed 10-15m from surface and then every 30m to bottom of hole.

### **Sampling and sub-sampling techniques**

Diamond core samples, either HQ3 or NQ2 in size diameter, were either cut in half longitudinally or a third longitudinally. Core sample intervals varied from 0.3m to 1.3m in length but were predominantly aligned to 1m intervals or with sample boundaries which respected geological contacts. RC drilling samples were collected in 1m downhole intervals by passing through a cyclone, a collection box and then dropping through a cone splitter. All RC sub-samples were collected over one metre downhole intervals and had an averaged mass of 3-4kg.

### **Sample Analysis Method**

Sample preparation included oven drying (105°C), crushing (<6mm), pulverising (P90% passing 75µm) and split to obtain a 50-gram catchweight. Analysis for gold only was carried out by Fire Assay fusion technique with AAS finish. Blanks and CRM standards were inserted in each sample batch at a ratio of 1:25. Field duplicates were typically collected at a ratio of 1:25 samples. Laboratory pulp grind and crush checks were typically requested at a ratio of 1:50 or less. Best practice QAQC methods for all drilling operations and the treatment and analysis of samples have been implemented and adhered to.

### **Estimation Methodology**

Gold grades have been estimated using Ordinary Kriging (OK) from a resource dataset of RC and Diamond drilling only. Samples have been flagged by estimation domain wireframes, assigned a unique domain identifier, and composited to 1m. Composites have been analysed for grade outliers and topcut as appropriate to minimise the Coefficient of Variation (CV). Variograms for well supported domains were created to analyse nugget values and the spatial continuity of the data and act as inputs to the OK estimations. All estimation parameters have been derived from Kriging Neighbourhood Analysis (KNA). Where lodes exhibit bi/multi-model grade populations, categorical indicator kriging (CIK) has been utilised to generate sub-domains within lodes prior to grade estimation using ordinary kriging.

The block model used in the CIK estimation has blocks set at 1x2x1m to ensure sub-domain complexity is maintained then optimised and re-blocked to the parent block size of 5mx5mx5m for parent cell size grade estimation with nested search passes employed informed by variogram ranges. The models have been depleted for historical mining where appropriate and bulk density has been assigned by weathering profile. Estimated grades have been validated both visually and statistically to ensure conformance to input sample data.

## Cut-off Grades

The in situ Mineral Resources have been reported above a 0.40g/t Au cut-off within an optimisation pit shell based on Measured, Indicated and Inferred Mineral Resources.

## Resource Classification

Classification is based on a combination of drill spacing, geological confidence and estimation quality. The Resource has been classified as Inferred, Indicated or Measured based on the following:

- ▶ Measured – Mined inventory only.
- ▶ Indicated - Blocks within interpreted mineralisation/estimation domains, containing more than 3 drill holes and more than 5 composite samples, at a drill spacing of 20mx20m or tighter.
- ▶ Inferred - Blocks within interpreted mineralisation/estimation domains at a drill spacing <40mx40m.

## Mining Assumptions

The open pit estimate has been undertaken on the assumption of open pit mining methods; the selection of SMU size was based on the scale of mining equipment likely to be used.

## Metallurgical Assumptions

Metallurgical assumptions were based on PFS level test work completed on Lewis and Kyte samples. Processing recoveries of 95% have been assumed for all material types.

## Other Modifying Factors

No modifying factors are applied to the Mineral Resource.

## BRUNO-LEWIS ORE RESERVES

The Bruno-Lewis Ore Reserve is based on the Mineral Resource and a Pre-Feasibility Study undertaken by Genesis Minerals. The Ore Reserve comprises of a three staged (central, south and north) pit design.

The Bruno-Lewis Ore Reserve has been estimated on a A\$2,800/oz gold price assumption. The Ore Reserve includes only Probable classifications. The economically mineable component of the Indicated Mineral Resource has been classified as a Probable Ore Reserve.

All ore in the Ore Reserve estimate is classified as a Probable Ore Reserve. No Inferred Mineral Resources are included in the Ore Reserve.

*Table 27: Bruno-Lewis Ore Reserve*

| Project     | Proved      |             |             | Probable    |             |             | Proved +Probable |             |             |

*Figure 18. Bruno-Lewis Reserve Pit Design*

### **Mining Method and Assumptions**

The Bruno-Lewis Reserves will be mined using 140t rear dump trucks and 200t & 100t hydraulic excavator mining fleets, using drill and blast on 5m benches and excavators operating on 2.5m flitches. Haul road widths of 27m for dual access roads and 16m for single access roads were used. Minimum mining width of 20m was used for cutbacks and pit benches with the exceptions of goodbye cuts that will be top loaded.

Mining of the pit will be carried out by Genesis Mining Services Pty Ltd (GMS), Genesis' 'internal mining contractor', utilising a mining fleet under an 'owner-operator' model. Leasing and ownership costs have been allocated across the life of the equipment asset. Operating costs for the fleet have been built up utilising the OEM guidance incorporating the operating strategy under the GMS ownership.

Final pit limits were determined from pit optimisations using Whittle Four-X software with inputs from the diluted Resource model, geotechnical parameters, metal prices, metallurgical recoveries, royalties, modifying mining factors and operating costs. Appropriate optimisation shells were selected to suit the operation, from which detailed pit designs and mine schedules were completed.

Ore dilution and mining recovery was modelled using minable shape optimisation (MSO) software to generate minable ore block designs. This accounts for planned ore loss and dilution. A skin was then applied to these ore blocks to account for unplanned ore loss and dilution.

A detailed Geotechnical assessment of the Bruno-Lewis deposit was carried out by geotechnical consultants Peter O'Bryan and Associates which recommended the wall angles and bench heights based on weathering zones and wall orientation. These recommendations were used as the basis for the pit designs.

### **Processing Method & Assumptions**

Bruno-Lewis ore is free milling and will primarily be processed through the existing Laverton processing plant. If opportunities arise or strategy dictates, then some Bruno-Lewis ore may be processed at the Gwalia processing plant. The 3.0Mtpa Laverton processing plant was commissioned in late March 2018 and includes a Semi-Autogenous Grinding, Ball Milling and Pebble Crushing (SABC) comminution circuit followed by a conventional gravity and carbon-in-leach (CIL) process. The Gwalia process plant consists of a 1.4Mtpa crushing and grinding circuit followed by a conventional gravity recovery and carbon-in-leach (CIL) circuit.

A metallurgical test work program has been undertaken for the Bruno-Lewis deposit and used as the basis for determining the milling recovery factors for the pit. All metallurgical test work programs were conducted on representative mineralised

composites prepared from diamond drill core. The average processing recovery for Bruno-Lewis is estimated to be 93%. There are no known occurrences of deleterious elements.

### **Cut-Off Grade**

Cut Off Grades were derived from cost estimates developed for the Pre-Feasibility Study. The cut-off grade used to define ore is the breakeven grade for variable processing and ore haulage costs and a share of the fixed costs for general and administration (G&A) through the Laverton and Gwalia processing plants. A cut-off grade of 0.5g/t was selected for Bruno-Lewis Reserves based on these calculations.

### **Tenure**

All tenements are 100%-owned by Genesis Minerals Limited's wholly-owned subsidiaries. All ore reserve estimates, and proposed mining activities are on granted mining leases that are in good standing.

### **Environmental Permitting and Approvals**

All environmental studies have been completed for the Bruno-Lewis Project and currently regulatory approvals and permits are required to commence mining. There are no known reasons to believe that these additional approvals will not be approved on time and prior to mining commencing.

### **Infrastructure**

The Bruno-Lewis deposit is located approximately 20km east of the Leonora township and is also within driving distance of Kalgoorlie, a major regional hub. Access to the site is via sealed public highways and private unsealed roads. The site workforce will be primarily fly-in, fly-out (FIFO) from Perth via the public Leonora airstrip. The workforce will utilise existing accommodation facilities available at the Genesis owned Leonora and Laverton villages.

The Project currently has mine offices, workshops and ablutions. The Project will establish, power, fuel storage, reverse osmosis, and wastewater treatment plants. Ore will be hauled using road trains to the existing Laverton processing plant via sealed public roads, and on occasion to the Gwalia processing plant.

### **Costs**

Surface infrastructure capital costs are derived from tenders or quotations and include fuel bay, ERT and First Aid facilities, and light vehicles, civils, HV workshop and other surface infrastructure. All capital infrastructure costs have a minimum 10% contingency applied.

Load and haul mining costs are built up from first principles by Genesis Mining Services based upon life of asset ownership costs and operating costs. Drill and blast costs are derived directly from tendered prices. Surface haulage costs were sourced from quotations received from reputable road haulage contractors that operate in the Goldfields region.

Accommodation is based on current rates for Genesis' accommodation facilities in Leonora. Flights are based on current chartered rates incurred by Genesis Minerals through the Leonora airport.

Processing and General and Administration costs are based on actual operating costs incurred at both the Laverton and Gwalia operations.

West Australian State Government royalty of 2.5% and third-party royalties of 1% were included.

### **Economic Outcomes**

The Ore Reserve estimate is based on a pre-feasibility level of accuracy with inputs from mining, processing, transportation, sustaining capital and contingencies scheduled and costed to generate the Ore Reserve cost model.

Load and haul mining costs are built up from first principles by Genesis Mining Services based upon life of asset ownership costs and operating costs. Drill and blast costs are derived directly from tendered prices. Road haulage costs are from budget rates supplied by a reputable goldfields haulage contractor. Site capital costs are sourced from tendered pricing

for infrastructure. Processing and general and administration (G&A) costs are sourced from the current operating costs at the Gwalia Mill and the most recent operating costs for the Laverton Mill.

The Ore Reserve returns an economic outcome based on the assumed commodity price and cost estimation, and the Competent Person is satisfied that the project economics that make up the Ore Reserve are suitable based on the mine design, modifying factors, assumptions, and environment.

Sensitivity analysis has indicated that the project drivers are gold price, mining and metallurgical recovery followed by operating expenditure.

## BEASLEY CREEK

### RESOURCES & RESERVES SUMMARY

Genesis' Mineral Resource Estimate for Beasley Creek of **6.7Mt at 2.0g/t for 0.43Moz** and an Ore Reserve Estimate of **4.5Mt at 1.7g/t for 0.24Moz**.

Key changes to the previously reported Mineral Resource and Ore Reserve:

- ▶ Additional drilling, geological interpretation review and re-estimation using the Categorical Indicator Kriging (CIK) technique prior to grade estimation with Ordinary Kriging (OK); and
- ▶ Increase in Indicated Mineral Resource classification material within the immediate vicinity of the previously reported Ore Reserve material.

### BEASLEY CREEK MINERAL RESOURCES

#### Geology and Geological Interpretation

The Beasley Creek deposit is an epigenetic, stratabound deposit located on the southern tip of the Windarra Batholith. The regional Chatterbox Shear Zone splays into Beasley Creek Shear with an approximately 45° counterclockwise strike change against the monzogranite. Gold mineralisation is dominantly hosted within severely weathered sedimentary packages up to 60m thick, bordered to the hanging wall and foot wall by tholeiitic basalt. The hanging wall mafic unit is overlaid by a schistose, talc-carbonate-altered ultramafic unit to the northeast. The mine sequence strikes north-south and dips 45-65° towards the east. Stratigraphy is folded with the antiformal fold axis plunging steeply south and exerts strong control on mineralisation. There exists a 300m gap between Beasley Creek South, previously known as Calypso, and Beasley Creek North with the separation attributed to barren, SW-NE trending Proterozoic dyke.

Mineralisation is characterized by abundant disseminated sulphides within polymictic breccia with strong ferruginisation. Regolith profile locally draws down along the mineralised horizon to vertical depths more than 200m. Shear lode drill intersections often appear strongly altered by goethitic and hematitic clay. Mineralisation continuity is approximately 1000m along strike and 400m down-dip.

#### Drilling Techniques

The deposits have principally been defined by a combination of diamond holes and reverse circulation (RC) drilling. RAB, air core (AC) holes, production blast holes (BH) and Sludge holes have also been completed. All drill types except for diamond and RC holes have been excluded from the MRE. All drill types have been used to guide the geological interpretation.

Diamond holes typically used NQ (47.6mm) and HQ (63.5mm) sized core. Recovery is recorded by the drillers on core blocks and compared to the measurements of the core by the geologist. Recovery is generally very high (>99%) through the host rocks. Diamond drilling has utilised triple-tubing through the expectant mineralised intervals to maximise recovery. Core is oriented using orientation tools to facilitate structural measurements and cut along a plane passing through the basal orientation mark using a diamond saw.

RC holes used 5½" reverse circulation face sampling hammers with samples typically taken at one metre intervals through a cone splitter. Most samples were dry, but where wet samples were encountered, they were allowed to dry before being split by company personnel.

### **Sampling and sub-sampling techniques**

Diamond core samples were cut in half longitudinally, with intervals from 0.3 to 1.3m in length but were predominantly aligned to 1m intervals or with sample boundaries which respected geological contacts. RC drilling samples were collected in 1m downhole intervals by passing through a cyclone, a collection box and then dropping through a cone splitter. All RC sub-samples were collected over one metre downhole intervals and had an averaged mass of 3-4kg.

### **Sample Analysis Method**

Current sample preparation and assay procedures employed by GMD are considered to follow industry standard practice. All assay determinations are conducted by internationally recognised laboratories. The primary laboratory meets ISO 9001:2000. Samples are oven dried until a constant mass is achieved. All samples are then processed through a jaw crusher to 90% passing < 3 mm. The crushed sample is then pulverised for 4 minutes in an LM5 pulveriser for a product of 90% passing < 75µm. Approximately 250 - 300g of the pulp is retained and a 40g charge weight for fire assay is extracted from the pulp packet. Samples are tested for sulphides and flux-adjusted, flux is added at a ratio of 1:4. Samples are fired, hammered and cupelled. Prills are placed in tubes, dissolved on hotplates and analysed using AA finish with over range dilutions.

### **Estimation Methodology**

All domains were estimated using ordinary kriging for grade estimation from a resource dataset of RC and diamond hole only. Samples have been flagged by estimation domain wireframes, assigned a unique domain identifier, and composited to 1m. Composites have been analysed for grade outliers and topcut as appropriate to minimise the Coefficient of Variation (CV). Variograms for well supported domains were created to analyse nugget values and the spatial continuity of the data and act as inputs to the OK estimations. All estimation parameters have been derived from Kriging Neighbourhood Analysis (KNA). Where lodes exhibit bi/multi-model grade populations, categorical indicator kriging (CIK) has been utilised to generate sub-domains within lodes prior to grade estimation using ordinary kriging.

The block model used in the CIK estimation has blocks set at 1x1x1m to ensure sub-domain complexity is maintained then optimised and re-blocked to the parent block size of 5mx5mx5m for parent cell size grade estimation with nested search passes employed informed by variogram ranges.

The models have been depleted for historical mining where appropriate and bulk density has been assigned by weathering profile and lithology. Estimated grades have been validated both visually and statistically to ensure conformance to input sample data.

### **Cut-off Grades**

The in situ resources have been reported within an optimised pit shell at a 0.40g/t Au cut-off based on Measured, Indicated and Inferred Mineral resources. No assumptions have been made for mining dilution.

### **Resource Classification**

The Mineral Resource is classified as Measured, Indicated, Inferred, or Potential (Unclassified) using the guidelines of the JORC Code (2012). The categories are assigned based on a combination of physical and estimation quality metrics including mining exposure, drill spacing, kriging metrics, grade and geological continuity. Resource categories are manually assigned to individual lodes via digitised string to the RESCAT attribute. Mineralisation has been categorised as Measured only if it has been exposed by mining. Indicated material is assigned if drill spacing is supported by up to 30mx30m, established grade and geological continuity from drilling and/or historical pit mapping. Inferred material is drill spacing supported by 60mx60m with limited geological continuity. All other mineralisation is assigned a Potential resource

category.

## Mining Assumptions

The open pit resource has been reported within an RPEEE shell for Indicated and Inferred material at a 0.4g/t cut-off. The underground resource has been reported as Indicated and Inferred material only within MSO solids beneath the RPEEE shell.

## Metallurgical Assumptions

Leach recovery testing completed by Focus Minerals Limited in 2019 returned satisfactory results ranging between 92.67% and 97.74%. Metallurgical testing by GMD is ongoing.

## Other Modifying Factors

No modifying factors are applied to the Mineral Resource.

## BEASLEY CREEK ORE RESERVES

The Beasley Creek Ore Reserve is based on the Mineral Resource and a Pre-Feasibility Study undertaken by Genesis Minerals. The Ore Reserve comprises of a three staged (central, south and north) pit design.

The Beasley Creek Ore Reserve has been estimated on a A\$2,800/oz gold price assumption. The Ore Reserve includes only Probable classifications. The economically mineable component of the Indicated Mineral Resource has been classified as a Probable Ore Reserve.

All ore in the Ore Reserve estimate is classified as a Probable Ore Reserve. No Inferred Mineral Resources are included in the Ore Reserve.

*Table 27: Beasley Creek Ore Reserve*

| Project       | Proved      |             |             | Probable    |             |             | Proved +Probable |             |             |
|---------------|-------------|-------------|-------------|-------------|-------------|-------------|------------------|-------------|-------------|
|               | Tonnes (kt) | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) | Tonnes (kt)      | Grade (g/t) | Ounce (koz) |
| Beasley Creek | -           | -           | -           | 4,500       | 1.7         | 240         | 4,500            | 1.7         | 240         |

*Table 28: Beasley Creek Comparison to Previous Ore Reserve*

| Project       | Reserve at 25 April 2025 |             |             | Reserve at 31 Dec 2025 |             |             | Variance    |             |             |
|---------------|--------------------------|-------------|-------------|------------------------|-------------|-------------|-------------|-------------|-------------|
|               | Tonnes (kt)              | Grade (g/t) | Ounce (koz) | Tonnes (kt)            | Grade (g/t) | Ounce (koz) | Tonnes (kt) | Grade (g/t) | Ounce (koz) |
| Beasley Creek | 3,500                    | 1.8         | 200         | 4,500                  | 1.7         | 240         | 1,000       | -0.1        | 40          |

The key material modifying factors and assumptions for the 2026 Ore Reserves are listed below;

- ▶ Update in the geological interpretations, changes from an OK to CIK Resource estimation methodology, and additional DD drill results have led to a change in the Resource model and material increase in Mineral Resource Estimation.
- ▶ Reserve gold price assumption of A\$2,800/oz.
- ▶ Revised mining methodology from underground to open pit and associated pit design and mine planning assumptions based on GMS owner operator model leads to the selection of larger mining fleets and owner mining approach, resulting in higher productivity rates and lower unit mining costs.
- ▶ Beasley Creek ore to be treated at Genesis' Laverton processing facility.

Beasley Creek life of mine Key Parameters are summarised in Table 29.

*Figure 18. Beasley Creek Reserve Pit Design*

### **Mining Method and Assumptions**

The Beasley Creek Reserves will be mined using 140t rear dump trucks and 200t & 100t hydraulic excavator mining fleets, using drill and blast on 5m benches and excavators operating on 2.5m flitches. Haul road widths of 27m for dual access roads and 16m for single access roads were used. Minimum mining width of 20m was used for cutbacks and pit benches with the exceptions of goodbye cuts that will be top loaded.

Mining of the pit will be carried out by Genesis Mining Services Pty Ltd (GMS), Genesis' 'internal mining contractor', utilising a mining fleet under an 'owner-operator' model. Leasing and ownership costs have been allocated across the life of the equipment asset. Operating costs for the fleet have been built up utilising the OEM guidance incorporating the operating strategy under the GMS ownership.

Final pit limits were determined from pit optimisations using Whittle Four-X software with inputs from the diluted Resource model, geotechnical parameters, metal prices, metallurgical recoveries, royalties, modifying mining factors and operating costs. Appropriate optimisation shells were selected to suit the operation, from which detailed pit designs and mine schedules were completed.

Ore dilution and mining recovery was modelled using minable shape optimisation (MSO) software to generate minable ore block designs. This accounts for planned ore loss and dilution. A skin was then applied to these ore blocks to account for unplanned ore loss and dilution.

A detailed Geotechnical assessment of the Beasley Creek deposit was carried out by geotechnical consultants Peter O'Bryan and Associates which recommended the wall angles and bench heights based on weathering zones and wall orientation. These recommendations were used as the basis for the pit designs.

### **Processing Method & Assumptions**

Beasley Creek ore is free milling and will primarily be processed through the existing Laverton processing plant. The 3.0Mtpa Laverton processing plant was commissioned in late March 2018 and includes a Semi-Autogenous Grinding, Ball Milling and Pebble Crushing (SABC) comminution circuit, followed by conventional gravity and carbon-in-leach (CIL) process.

A reasonable quantity of test work has been conducted at Beasley Creek in several campaigns over many years. Additional metallurgical test work will provide more confidence in the performance of the milling circuit and gold recoveries.

The Laverton processing plant is considered capable of successfully handling the Laverton oxide and transition ores as well as selected primary ore types. Primary ores from have been excluded from the Ore Reserve.

Ores from Beasley Creek have been successfully processed in a number of processing operations, including the Barnicoat mill, providing confidence in the proposed outcomes.

The average processing recovery for Beasley Creek is estimated to be 91%. There are no known occurrences of deleterious elements.

### **Cut-Off Grade**

Cut Off Grades were derived from cost estimates developed for the Pre-Feasibility Study. The cut-off grade used to define ore is the breakeven grade for variable processing and ore haulage costs and a share of the fixed costs for general and administration (G&A) through the Laverton and Gwalia processing plants. A cut-off grade of 0.5g/t was selected for Beasley Creek Reserves based on these calculations.

### **Tenure**

All tenements are owned by Genesis Minerals Limited's wholly-owned subsidiaries. All ore reserve estimates, and proposed mining activities are on granted mining leases that are in good standing.

### **Environmental Permitting and Approvals**

Environmental studies relating to the re-commencement of mining operations are yet to commence, however there are no known reasons to believe that this additional approval will not be approved on time and prior to mining commencing.

### **Infrastructure**

The Beasley Creek deposit is located approximately 8km east of the Laverton township and is also within driving distance of Kalgoorlie, a major regional hub. Access to the site is via sealed public highways and private unsealed roads. The site workforce will be primarily fly-in, fly-out (FIFO) from Perth via the public Leonora airstrip. The workforce will utilise existing accommodation facilities available at the Genesis owned Laverton villages.

The Project will establish office, workshop, ablutions, power, fuel storage, reverse osmosis, and wastewater treatment plants. Ore will be hauled using road trains to the existing Laverton processing plant via sealed public roads.

### **Costs**

Surface infrastructure capital costs are derived from tenders or quotations and include a fuel bay, ERT and First Aid facilities, light vehicles, civils, heavy vehicle workshop and other surface infrastructure. All capital infrastructure costs have a minimum 10% contingency applied.

Load and haul mining costs are built up from first principles by Genesis Mining Services based upon life of asset ownership costs and operating costs. Drill and blast costs are derived directly from tendered prices. Surface haulage costs were sourced from quotations received from reputable road haulage contractors that operate in the Goldfields region.

Accommodation is based on current rates for Genesis' accommodation facilities in Laverton. Flights are based on current chartered rates incurred by Genesis Minerals through the Leonora airport.

Processing and General and Administration costs are based on actual operating costs incurred at both the Laverton and Gwalia operations.

West Australian State Government royalty of 2.5% and third-party royalties of 1% were included.

### **Economic Outcomes**

The Ore Reserve Estimate is based on a pre-feasibility level of accuracy with inputs from mining, processing, transportation, sustaining capital and contingencies scheduled and costed to generate the Ore Reserve cost model.

Load and haul mining costs are built up from first principles by Genesis Mining Services based upon life of asset ownership costs and operating costs. Drill and blast costs are derived directly from tendered prices. Road haulage costs are from budget rates supplied by a reputable goldfields haulage contractor. Site capital costs are sourced from tendered pricing for infrastructure. Processing and G&A costs are sourced from the current operating costs at the Laverton Mill.

The Ore Reserve returns an economic outcome based on the assumed commodity price and cost estimation, and the Competent Person is satisfied that the project economics that make up the Ore Reserve are suitable based on the mine design, modifying factors, assumptions, and environment.

Sensitivity analysis has indicated that the project drivers are gold price, mining and metallurgical recovery followed by operating expenditure.

## Forward-looking statements

Some statements in this announcement regarding estimates or future events are forward-looking statements. They include indications of, and guidance on, future matters. Forward-looking statements include, but are not limited to, statements preceded by words such as “planned”, “expected”, “projected”, “estimated”, “may”, “scheduled”, “intends”, “anticipates”, “believes”, “potential”, “could”, “nominal”, “conceptual” and similar expressions. Forward-looking statements, opinions and estimates included in this Presentation are based on assumptions and contingencies which are subject to change without notice, as are statements about market and industry trends, which are based on interpretations of current market conditions.

Forward-looking statements are provided as a general guide only and should not be relied on as a guarantee of future performance. Forward-looking statements may be affected by a range of variables that could cause actual results to differ from estimated results and may cause Genesis’ actual performance and financial results in future periods to materially differ from any projections of future performance or results expressed or implied by such forward-looking statements. These risks and uncertainties include but are not limited to liabilities inherent in mine development and production, geological, mining and processing technical problems, the inability to obtain any additional mine licenses, permits and other regulatory approvals required in connection with mining and third party processing operations, competition for among other things, capital, acquisition of reserves, undeveloped lands and skilled personnel, incorrect assessments of the value of acquisitions, changes in commodity prices and exchange rate, currency and interest fluctuations, various events which could disrupt operations and/or the transportation of mineral products, including labour stoppages and severe weather conditions, the demand for and availability of transportation services, the ability to secure adequate financing and management’s ability to anticipate and manage the foregoing factors and risks. These and other factors should be considered carefully and readers should not place undue reliance on such forward-looking information. There can be no assurance that forward-looking statements will prove to be correct.

## Competent Persons Statement

The information in this report that relates to Exploration Results is based on information, and fairly represents, information and supporting documentation compiled by Mr. Andrew Chirnside who is a Member of the Australasian Institute of Mining and Metallurgy. Andrew Chirnside is a full-time employee of Genesis Minerals Limited and holds securities in the Company. Andrew Chirnside has sufficient experience relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the “Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves”. Andrew Chirnside consents to the inclusion in the statement of the matters based on his information in the form and context in which it appears.

The information in this report that relates to Mineral Resources is based on information, and fairly represents, information and supporting documentation compiled by Mr Timothy Sanders who is a Member of the Australian Institute of Geoscientists. Timothy Sanders is a full-time employee of Genesis Minerals Limited and holds securities in the Company. Timothy Sanders has sufficient experience relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the “Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves”. Timothy Sanders consents to the inclusion in the statement of the matters based on his information in the form and context in which it appears.

The information in this report that relates to Ore Reserves at Tower Hill, Beasley Creek, Admiral and Hub Open Pits is based on information, and fairly represents, information and supporting documentation compiled by Mr Matthew Isaacs who is a Member of the Australasian Institute of Mining and Metallurgy. Matthew Isaacs is a full-time employee of Genesis Minerals Limited and holds securities in the Company. Matthew Isaacs has sufficient experience relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the “Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves”. Matthew Isaacs consents to the inclusion in the statement of the matters based on his information in the form and context in which it appears.

The information in this report that relates to Ore Reserves at Westralia Open Pits is based on information, and fairly represents, information and supporting documentation compiled by Mr. Christopher Burton who is a Member of the Australasian Institute of Mining and Metallurgy. Christopher Burton is a full-time employee of Genesis Minerals Limited and holds securities in the Company. Mr Burton has sufficient experience relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the “Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves”. Christopher Burton consents to the inclusion in the statement of the matters based on his information in the form and context in which it appears.

The information in this report that relates to Ore Reserves at Gwalia and Ulysses Underground is based on information, and fairly represents, information and supporting documentation compiled by Mr Jonathan Wall who is a Member of the Australasian Institute of Mining and Metallurgy. Jonathan Wall is a full-time employee of Genesis Minerals Limited and holds securities in the Company. Jonathan Wall has sufficient experience relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the “Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves”. Jonathan Wall consents to the inclusion in the statement of the matters based on his information in the form and context in which it appears.

The information in this report that relates to Ore Reserves at Beasley Creek, Karridale, Lancefield, Bruno-Lewis, GTS, Jupiter, Orient Well, Puzzle, Ulysses Open Pits and Zoroastrian Underground is based on information, and fairly represents, information and supporting documentation compiled by Mr. Tristan Sommerford who is a Member of the Australasian Institute of Mining and Metallurgy. Tristan Sommerford is a full-time employee of Genesis Minerals Limited and holds securities in the Company. Tristan Sommerford has sufficient experience relevant to the style of

mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the "Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves". Tristan Sommerford consents to the inclusion in the statement of the matters based on his information in the form and context in which it appears.

### **No Liability**

Genesis Minerals Limited has prepared this announcement based on information available to it. No representation or warranty, express or implied, is made as to the fairness, accuracy, completeness or correctness of the information, opinions or conclusions contained in this announcement. To the maximum extent permitted by law, none of Genesis Minerals Limited, its directors, officers, employees, associates, advisers and agents, nor any other person accepts any liability, including, without limitation, any liability arising from fault or negligence on the part of any of them or any other person, for any loss arising from the use of this announcement or its contents or otherwise arising in connection with it.

This announcement is not an offer, invitation, solicitation, or other recommendation with respect to the subscription for, purchase or sale of any security, and neither this announcement nor anything in it shall form the basis of any contract or commitment whatsoever.

Table 20: Detailed Group Resources

**Notes**

All figures reported to two significant figures. Rounding errors may occur.

Mineral Resources are inclusive of Ore Reserves.

Mineral Resources are reported at various gold price guidelines between A\$2500 and A\$3500/oz Au.

Rounding may result in apparent summation differences between tonnes, grade and contained metal content.

All figures reported to two significant figures. Rounding errors may occur.

Ore Reserves are based on a gold price of A\$2,800/ounce

## Appendix 1 - JORC TABLE 1s

### JORC Table 1 Checklist of Assessment and Reporting Criteria – Gwalia Section 1 Sampling Techniques and Data – Gwalia

| Criteria                                              | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sampling Techniques</b>                            | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>Surface and underground diamond core is primarily NQ (50.6mm) sized core, sampled to max 1.3m intervals or geological boundaries where necessary and cut into half core. The upper or right-hand side of the core is routinely submitted for sample analysis, with each one metre of half core providing between 2.5 – 3kg of material as an assay sample. Minimum sample length is 0.30 m for DD core.</li> <li>RC chips are cone or riffle split and sampled into 1m intervals.</li> <li>All sampling methods are used to produce representative sample of less than 3kg. Samples are selected to weigh less than 3kg to ensure total sample inclusion at the pulverisation stage.</li> <li>Genesis core and chip samples are crushed, dried and pulverised to a nominal 85% passing 75µm to produce a 40g or 50g sub sample for analysis by FA/AAS.</li> <li>Visible gold is sometimes encountered in underground drill core.</li> <li>Historical AC, RAB, RC and diamond sampling was carried out to industry standard at that time. Analysis methods include fire assay and unspecified methods.</li> </ul> |
| <b>Drilling Techniques</b>                            | <ul style="list-style-type: none"> <li>Drill type (e.g., core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g., core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <ul style="list-style-type: none"> <li>Drill holes used in the estimate include 3,976 diamond holes (DDH), 650 reverse circulation holes and 14 diamond holes collared from surface with RC pre-collars (RCD). In addition, large numbers of regional RAB (Rotary Air Blast) and air-core (AC) holes have been completed but excluded from the estimation due to lower sample quality.</li> <li>Diamond core is oriented using Reflex ACT II/III Orientation tool. Some historic diamond drill core appears to have been oriented by unknown methods.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Drill Sample Recovery</b>                          | <ul style="list-style-type: none"> <li>Method of recording and assessing core and chip sample recoveries and results assessed.</li> <li>Measures taken to maximise sample recovery and ensure representative nature of the samples.</li> <li>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <ul style="list-style-type: none"> <li>RC sampling recoveries are recorded in the database as a percentage based on a visual weight estimate; no historic recoveries have been recorded.</li> <li>Diamond core recovery percentages calculated from measured core versus drilled intervals are logged and recorded in the database. Recoveries average &gt;95%.</li> <li>There is no known relationship between sample recovery and grade for RC drilling.</li> <li>Diamond drilling has high recoveries due to the competent nature of the ground meaning loss of material is minimal.</li> <li>Underground diamond drilling through historic workings is carefully assessed and driller core blocks checked to ensure that cave in and backfill material is not treated as an 'in situ' sample.</li> </ul>                                                                                                                                                                                                                                                                                                                                            |
| <b>Logging</b>                                        | <ul style="list-style-type: none"> <li>Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.</li> <li>Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.</li> <li>The total length and percentage of the relevant intersections logged.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <ul style="list-style-type: none"> <li>Logging of RC chips and diamond drill core records lithology, mineralogy, texture, mineralisation, weathering, alteration and veining.</li> <li>Geotechnical and structural logging is carried out on all diamond holes to record recovery, RQD, defect number, type, fill material, shape and roughness and alpha and beta angles (where core is oriented).</li> <li>Core is photographed in both dry and wet state after logging and prior sampling.</li> <li>Qualitative and quantitative logging of historic data varies in its completeness.</li> <li>All diamond drillholes and exploration RC holes are logged in full.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Sub-sampling techniques and sample preparation</b> | <ul style="list-style-type: none"> <li>If core, whether cut or sawn and whether quarter, half or all core taken.</li> <li>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</li> <li>For all sample types, the nature, quality, and appropriateness of the sample preparation technique.</li> <li>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</li> <li>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <ul style="list-style-type: none"> <li>All drill core is cut in half onsite using Almonte automatic core saw. Samples are always collected from the same side.</li> <li>Historic diamond drilling has been mostly half core sampled, however some GC diamond drilling has been full core sampled in certain time periods.</li> <li>All exploration and GC RC samples are cone or riffle split. Occasional wet samples are encountered; increased air capacity is routinely used to aid in keeping the sample dry when water is encountered.</li> <li>Historic AC, RAB and RC drilling was sampled using spear, grab, riffle and unknown methods.</li> <li>The sample preparation of diamond core and RC chips adhere to industry best practice. It is conducted by a commercial laboratory and involves oven drying, coarse crushing then total grinding to a size of 85% passing 75</li> </ul>                                                                                                                                                                                                                                                         |

| <b>Exploration Done by Other Parties</b>       | <ul style="list-style-type: none"> <li>Acknowledgment and appraisal of exploration by other parties.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                  | <ul style="list-style-type: none"> <li>Discovered in 1896, the Sons of Gwalia ore body was mined by underground methods until 1963, when the mine had reached a vertical depth of 1,075m at the 32 level.</li> <li>In 1983 Sons of Gwalia Ltd, (SGW) acquired the leases over the mine, and commenced open pit mining soon after in 1984. Mining by open pit methods continued until January 1999 with the pit extending to 280m vertical depth. Underground mining, largely of remnant ore, commenced at the completion of open cut mining and ceased in September 2003 at a vertical depth of 375m.</li> <li>Initial exploratory drilling of the Gwalia Deeps ore body was subsequently undertaken between March 1986 and May 1989 as a jointly funded project by WMC and SGW. Four deep diamond drill holes and two wedge holes were drilled between 1,200m – 1,400m vertical depth.</li> <li>Western Mining Corporation, (WMC) first investigated the possibility of testing resource extensions below 1,075mbs in 1965, (Parbo, 1965), however the economics did not support the exploration proposal.</li> <li>In 1998, SGW began phase I of the Gwalia Deeps drilling program, (Quinney &amp; Culpan, 1998). This consisted of two parent holes (GWDD5 and GWDD6) and 5 daughter holes (GWDD6A – E), targeting mineralisation between 1,200m – 1,300m vertical depth.</li> <li>SGW commenced a phase II program in 2000, completing a further four parent holes GWDD7 – GWDD10 and a further 5 daughter holes.</li> <li>The mine was acquired by SBM in March 2005 with further deep drilling, targeting resource extensions below 1,075mbs, commencing later the same year and continuing through until early 2007.</li> <li>Drilling targeting resource extensions below 1,600mbs to 2,000mbs commenced in August 2010 and was completed in July 2011. Due to the success of these programs further drilling was completed between November 2011 and March 2012 aimed at infilling and extending the South Gwalia Series (SGS) and South-West Branch (SWB) resources below 1600mbs (Evans, 2012).</li> </ul> |
| <b>Geology</b>                                 | <ul style="list-style-type: none"> <li>Deposit type, geological setting and style of mineralisation.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                  | <ul style="list-style-type: none"> <li>The Sons of Gwalia deposit lies in the central portion of the Norseman-Wiluna Archaean Greenstone Belt. The greenstone belt here comprises an arcuate, low strain mafic-ultramafic succession folded around the eastern and northern margin of the Raeside Batholith.</li> <li>Locally, the deposit lies in the Gwalia Domain which Witt, (1997) defines as bound by the Mount George Shear Zone to the east, the Sons of Gwalia Shear Zone to the west and south and the Clifford Fault to the north.</li> <li>The Sons of Gwalia mineralised zone strikes 15 degrees east of true north over 500m and plunges 45 degrees to the southeast. The mineralised zone is essentially a series of folded extensional veins that form a broad 'M' fold geometry, with the hold hinge positioned at the southern end (also plunging southeast). The mineralised footprint most simply resembles a horseshoe.</li> <li>The individual lodes are a few metres to tens of metres thick consisting of gold-bearing quartz-carbonate veins that vary in size from millimetres to metres thick. These veins are folded, stretched (boudinaged), and laminated, and they sit inside a wide zone of strongly deformed, east-dipping basalt schist called the "mine schist".</li> <li>The most consistent and clearest correlation of gold grade at all levels and in all lodes is with 'recrystallized' quartz abundance. Sulphide mineralisation (mostly pyrite, rarer pyrrhotite) may present in the lodes in disseminated or vein</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

The primary database is regulated by a locked framework which fixes the relationships between tables. The data model minimises the potential for data collection and data usage errors through pre-determined look up tables, storage and export functions.</li> <li>User defined permissions also regulate the ability to add, edit or extract data.</li> <li>Primary data is recorded using typical manual translation of logging and data capture from written logs and direct import of csv tables through a data import scheme where data is validated upon import or direct data entry options into the database using predefined look up values.</li> <li>Core logging data is entered and primary validation pass conducted in LogChief software and the data is synchronized in Datashed database.</li> <li>Data that is captured in the field is entered into Excel templates which are checked on import into the database for errors. Assay jobs are dispatched electronically to the lab to minimise the chance of data entry errors. Assay results from the lab are received in CSV and PDF format and are checked for errors on import into the database. Data is regularly validated using the mining software. The data validation process is overseen by the Database Administrator.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

All domain wireframes are created using Leapfrog software and all subsequent estimation is completed using Datamine software. Lode wireframes are intersected with a validated drill database from which all RAB, air core, and erroneous drill holes have been removed. All remaining diamond, and RC samples are flagged with a domain identifier and composited to 1m with 0.3m minimum sample. Residual samples are distributed across adjacent component intervals. Composites are analysed for population outliers by domain and are topcut proximal to population disintegration. The top-cut process affects only 1-2% of the data. Some of the principal lodes exhibit bi/multi-modal grade populations. These internal populations are controlled by grade indicators based on inflexion points derived from domain log probability plots from which indicator variograms are created. Categorical indicator kriging (CIK) is then used to sub-domain lodes with mixed populations. The block model used in the CIK estimation has blocks set at 1x1x2m to ensure sub-domain complexity is maintained then optimised and re-blocked to the parent block size of 5x5x5m. This model is then used to back flag the composite file with the defined sub-domain identifiers. Variography is created for all domains and sub-domains with sufficient sample data. Output variograms are utilised in kriging neighbourhood analysis (KNA) to generate optimum parent block sizes and estimation parameters. Domains and sub-domains are estimated using ordinary kriging utilising the estimation parameters defined in the KNA as inputs. Grade is estimated into parent blocks only and all kriging quality metrics and search pass values are output. The maximum distance of extrapolation from last known data points for the inferred material is dependent on the geological continuity and confidence across the lode, but less than 40m for the deposit.</li> <li>The Mineral Resource Estimation is checked against the previous block model estimations and reconciled production numbers on a monthly and yearly basis.</li> </ul> |

| Criteria                                    | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                             | <i>model data to drill hole data, and use of reconciliation data if available.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <ul style="list-style-type: none"> <li>No assumptions are made regarding the recovery of by-products for this Mineral Resource Estimation.</li> <li>No estimation of deleterious elements or non-grade variables is required.</li> <li>The model has been created using a parent cell size of 5m (East- West) x 5m (North-South) x 5m (vertical) optimised using quantitative kriging neighbourhood analysis. Sub-cells have been used at a resolution of 1m x 1m x1m to ensure high resolution at ore boundaries. The search distances are dictated by the range of each individual variogram but typically equate to 1-1.5 times the current 50x50m resource definition spacing. A 3rd pass nested search strategy is employed with the first pass always set to the full range of the variogram. The second pass is set at 2-3 times the variogram range with the final pass set at a factor large enough to ensure all blocks comprising the domain are estimated.</li> <li>No assumptions have been made regarding the modelling of selective mining units for this Mineral Resource Estimation</li> <li>No assumptions have been made regarding the correlation between variables for this Mineral Resource Estimation.</li> <li>Mineralisation is partitioned into estimation domains relative to stratigraphic position, structural orientation, recorded lithology and specific alteration assemblage. The geological interpretation is initially created from drill data and later calibrated with mapping from open pit and underground exposures. Domains are estimated individually with search geometry and variography controlled by lode orientation and grade continuity respectively. Variogram major search directions are aligned with geologically interpreted high grade shoot trends. Categorical indicator kriging has been utilised to define sub-domains in lodes with mixed grade populations to limit the spread of high-grade mineralisation. Dynamic anisotropy has been employed on all lodes due to the common nature to exhibiting excessive undulation defined by localised variations mainly in the dip but sometimes the dip direction too. Boundary analysis has been conducted on key lodes indicating hard boundaries can be maintained across domain and sub-domain contacts.</li> <li>Samples with extreme high grades that bias the mean and positively skew the grade population within each domain are topcut to reduce the influence of high-grade outliers. Log probability plots and the coefficient of variation statistic are used to determine topcuts. Topcuts are typically set proximal to population disintegration.</li> <li>Several statistical and visual measures are used to validate the accuracy of the estimation. Volume variance between the wireframe domains and block model domains are assessed. A visual inspection of input composites is compared to the estimated block model in section for each domain. The mean grade of the block model is compared to the naïve and declustered mean grades of the composites by domain with any variance greater than 10% investigated. Swath plots are created by domain and sub-domain in the X, Y, Z, strike and cross strike directions and viewed holistically to vector into any problematic areas. Kriging efficiency, and slope results are reviewed by domain/sub-domain to give an indication of the quality of the estimate. Global change of support plots are created and reviewed for principal domains. End of month production and individual stope reconciliations in addition to ongoing field observations are used as a feedback loop to continuously calibrate and improve the interpretation and estimation.</li> </ul> |

| <b>Mining Factors or Assumptions</b>                            | <ul style="list-style-type: none"> <li>The method and assumptions used as reported in the Pre-Feasibility or Feasibility Study to convert the Mineral Resource to an Ore Reserve (i.e., either by application of appropriate factors by optimisation or by preliminary or detailed design).</li> <li>The choice, nature and appropriateness of the selected mining method(s) and other mining parameters including associated design issues such as pre-strip, access, etc.</li> <li>The assumptions made regarding geotechnical parameters (eg pit slopes, stope sizes, etc), grade control and pre-production drilling.</li> <li>The major assumptions made, and Mineral Resource model used for pit and stope optimisation (if appropriate).</li> <li>The mining dilution factors used.</li> <li>The mining recovery factors used.</li> <li>Any minimum mining widths used.</li> <li>The manner in which Inferred Mineral Resources are utilised in mining studies and the sensitivity of the outcome to their inclusion.</li> <li>The infrastructure requirements of the selected mining methods.</li> </ul> | <ul style="list-style-type: none"> <li>The Gwalia Ore Reserve has been estimated based on detailed mine development and stope designs. Modifying factors for dilution and mining recovery have been applied post-geological interrogation to generate the final diluted and recovered Ore Reserve.</li> <li>The Gwalia Mine is in full production with an extensive production history. Mining methods referenced in this report are currently in practice on site or have been subject to trial mining. Reconciliation results and production history show this mining method to be well matched to the ore body.</li> <li>Stope size, development placement and ground support strategies have been designed in line with recommendations from experienced geotechnical personnel and external subject matter experts. Grade control drilling is completed in advance of production with many stopes to be mined in the next two years already grade control drilled.</li> <li>A review of dilution was conducted of stope performance and no discernible difference was noted between lodes or depth below surface. Correlation was found to stope size and values used range from 28% for stopes less than 5kt to 16% for stopes exceeding 25kt. The average of the estimated dilution for all stopes in the Ore Reserve is 22%</li> <li>A 92% mining recovery factor has been applied to triple-lift and double-lift long-hole open stopes. A 90% mining recovery factor has been applied to single-lift long-hole open stopes. These factors are consistent with reconciled actual performance.</li> <li>The profiles of development excavations have been designed inclusive of 10% overbreak. No further dilution factors or mining recovery factors have been applied to development ore.</li> <li>A global minimum mining width of 3m is used. While the ore body width generally exceeds the minimum mining width, where the ore body is narrower stoping outlines are designed to honour the minimum width and include planned dilution.</li> <li>All ore in the Ore Reserve estimate is classified as a Proved or Probable Ore Reserve. No Inferred Mineral Resources are included in the Ore Reserve. The Inferred Mineral Resources in the Life-of-Mine plan have been removed from the Ore Reserve plan and estimate. A separate Inventory Life-of-Mine plan has also been developed inclusive of inferred material for purposes of strategic planning and to ensure that adequate allowances are made to not preclude mining should resource-reserve conversion prove favourable.</li> <li>The infrastructure requirements of the stoping methods used are either already in place or have been accounted for in the Life-of-Mine evaluation on which the project costings are based. The capital and operating costs of extending the ventilation infrastructure to support truck haulage down to the base of the Ore Reserve have been included in the</li> </ul> |

GMD undertook internal reviews into systems and processes.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Discussion of relative accuracy/confidence</b> | <ul style="list-style-type: none"> <li>Where appropriate a statement of the relative accuracy and confidence level in the Ore Reserve estimate using an approach or procedure deemed appropriate by the Competent Person. For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the reserve within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors which could affect the relative accuracy and confidence of the estimate.</li> <li>The statement should specify whether it relates to global or local estimates, and, if local, state the relevant tonnages, which should be relevant to technical and economic evaluation. Documentation should include assumptions made and the procedures used.</li> <li>Accuracy and confidence discussions should extend to specific discussions of any applied Modifying Factors that may have a material impact on Ore Reserve viability, or for which there are remaining areas of uncertainty at the current study stage.</li> <li>It is recognised that this may not be possible or appropriate in all circumstances. These statements of relative accuracy and confidence of the estimate should be compared with production data, where available.</li> </ul> | <ul style="list-style-type: none"> <li>The Ore Reserve estimate has been prepared in accordance with the guidelines of the JORC Code (2012). The relative confidence of the estimates contained fall with the criteria of Proved and Probable Ore Reserves. Significant operating history supports the modifying factors applied.</li> <li>The Ore Reserve has been estimated in line with the Genesis Minerals Ore Reserve process. The Ore Reserve process was externally audited in 2019 and found to be of good industry standard. The Ore Reserve has been peer reviewed internally and the Competent Person is confident that it is an accurate estimation of the current Gwalia reserve.</li> </ul> |

## JORC Table 1 Checklist of Assessment and Reporting Criteria – HARBOUR LIGHTS

### Section 1 Sampling Techniques and Data – Harbour Lights

| Criteria                                              | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sampling Techniques</b>                            | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>Sampling boundaries are geologically defined and one metre in length unless a significant geological feature warrants a change from this standard unit. The upper or right-hand side of the core is routinely submitted for sample analysis, with each one metre of half core providing between 2.5 – 3kg of material as an assay sample. Minimum sample length is 0.30 m.</li> <li>The majority of the drilling was completed by Esso Exploration and Production Australia Inc. (Esso) between 1981 and 1985. Diamond and RC holes have generally been sampled on 1m intervals but no details on sampling protocols have been found.</li> </ul> |
| <b>Drilling Techniques</b>                            | <ul style="list-style-type: none"> <li>Drill type (e.g. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g. core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <ul style="list-style-type: none"> <li>Diamond drill holes used NQ2 (50.6mm) sized core (standard tubes). Surface drill holes have been down hole surveyed by north seeking gyro. Holes are orientated using a Reflex ACT II RD orientation tool.</li> <li>Details of earlier RC and DDH drilling techniques have not been located. Diamond holes were surveyed by single shot camera.</li> </ul>                                                                                                                                                                                                                                                                                       |

External reviews are completed approximately every 3 years.</li> <li>The model was peer reviewed internally and by AMC consultants with no material issues identified.</li> </ul>                                         |
| <b>Discussion of relative accuracy/confidence</b> | <ul style="list-style-type: none"> <li>Where appropriate a statement of the relative accuracy and confidence level in the Mineral Resource estimate using an approach or procedure deemed appropriate by the Competent Person. For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the resource within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors that could affect the relative accuracy and confidence of the estimate.</li> <li>The statement should specify whether it relates to global or local estimates, and, if local, state the relevant tonnages, which should be relevant to technical and economic evaluation. Documentation should include assumptions made and the procedures used.</li> <li>These statements of relative accuracy and confidence of the estimate should be compared with production data, where available.</li> </ul> | <ul style="list-style-type: none"> <li>The resource estimate is a global estimate. Grade control drilling will be required to define local ore/waste boundaries during open pit mining.</li> </ul>                                                                                                                                                                                                                              |

## JORC Table 1 Checklist of Assessment and Reporting Criteria – Ulysses

### Section 1 Sampling Techniques and Data – Ulysses

| Criteria                                              | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sampling Techniques</b>                            | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>Surface and underground diamond core is NQ (50.6mm) sized core, sampled to 1m intervals or geological boundaries where necessary and cut into half core. The upper or right-hand side of the core is routinely submitted for sample analysis, with each one metre of half core providing between 2.5 – 3kg of material as an assay sample. Minimum sample length is 0.30 m for DD core.</li> <li>RC chips are cone or riffle split and sampled into 1m intervals.</li> <li>All sampling methods are used to produce representative sample of less than 3kg. Samples are selected to weigh less than 3kg to ensure total sample inclusion at the pulverisation stage.</li> <li>Genesis core and chip samples are crushed, dried and pulverised to a nominal 90% passing 75µm to produce a 40g or 50g sub sample for analysis by FA/AAS.</li> <li>Historical AC, RAB, RC and diamond sampling was carried out to industry standard at that time. Analysis methods include fire assay and unspecified methods.</li> </ul> |
| <b>Drilling Techniques</b>                            | <ul style="list-style-type: none"> <li>Drill type (e.g., core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g., core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <ul style="list-style-type: none"> <li>Drill holes used in the estimate include 367 diamond holes (DDH), 1,197 reverse circulation holes and 464 face channel samples. In addition, large number of regional RAB (Rotary Air Blast) and air-core (AC) holes have been completed but excluded from the estimation due to lower sample quality.</li> <li>DDH typically used NQ (47.6mm) and HQ (63.5mm) sized core (standard double tubes).</li> <li>Core was oriented using Ace Core Orientation and Ezy Mark orientation tools.</li> <li>Drill holes were down hole surveyed by either north seeking gyro within the rods or by electronic multi-shot in open holes. Less than 10% of holes were surveyed down hole using a Reflex Single Shot camera.</li> <li>RC holes used mainly 5½" reverse circulation face sampling hammers.</li> </ul>                                                                                                                                                                                                                |

|                 | <p><i>interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</i></p> <ul style="list-style-type: none"> <li><i>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</i></li> <li><i>The assumptions made regarding recovery of by-products.</i></li> <li><i>Estimation of deleterious elements or other non-grade variables of economic significance (e.g., sulphur for acid mine drainage characterization).</i></li> <li><i>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</i></li> <li><i>Any assumptions behind modelling of selective mining units.</i></li> <li><i>Any assumptions about correlation between variables.</i></li> <li><i>Description of how the geological interpretation was used to control the resource estimates.</i></li> <li><i>Discussion of basis for using or not using grade cutting or capping.</i></li> <li><i>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</i></li> </ul> | <ul style="list-style-type: none"> <li>Lode wireframes are intersected with a validated drill database from which all RAB, air core, and erroneous drill holes have been removed. All remaining diamond and RC samples are flagged with a domain identifier and composited to 1m with 0.3m minimum sample. Residual samples are distributed across adjacent component intervals.</li> <li>Composites are analysed for population outliers by domain and are topcut proximal to population disintegration. The top-cut process affects only 1-2% of the data.</li> <li>Many of the principal lodes exhibit bi/multi-model grade populations. These internal populations are controlled by grade indicators based on inflexion points derived from domain log probability plots from which indicator variograms are created. Categorical indicator kriging (CIK) is then used to sub-domain lodes with mixed populations. The block model used in the CIK estimation has blocks set at 1x2x1m to ensure sub-domain complexity is maintained then optimised and re-blocked to the parent block size of 5x10x5m. This model is then used to back flag the composite file with the defined sub-domain identifiers.</li> <li>Variography is created for all domains and sub-domains with sufficient sample data. Output variograms are utilised in kriging neighbourhood analysis (KNA) to generate optimum parent block sizes and estimation parameters.</li> <li>Domains and sub-domains are estimated using ordinary kriging utilising the estimation parameters defined in the KNA as inputs. Grade is estimated into parent blocks only and all kriging quality metrics and search pass values are output. The maximum distance of extrapolation from last known data points for the inferred material is dependent on the geological continuity and confidence across the lode, but less than 80m for the deposit.</li> <li>Search distances are dictated by the range of each individual variogram but typically equate to 1-1.5 times the current 40x40m resource definition spacing. A 3-pass nested search strategy is employed with the first pass always set to the full range of the variogram. The second pass is set at 2 times the variogram range with the final pass set at a factor large enough to ensure all blocks comprising the domain are estimated.</li> <li>The Mineral Resource Estimation is checked against the previous block model estimations following any material update.</li> <li>No assumptions are made regarding the recovery of by-products for this Mineral Resource Estimation.</li> <li>No estimation of deleterious elements or non-grade variables is required.</li> <li>No assumptions have been made regarding the modelling of selective mining units for this Mineral Resource Estimation</li> <li>No assumptions have been made regarding the correlation between variables for this Mineral Resource Estimation.</li> <li>Mineralisation is partitioned into estimation domains relative to stratigraphic position, structural orientation, recorded lithology and specific alteration assemblage. The geological interpretation is initially created from drill data and later calibrated with mapping from open pit exposures.</li> <li>Domains are estimated individually with search geometry and variography controlled by lode orientation and grade continuity respectively. Variogram major search directions are aligned with geologically interpreted high grade shoot trends.</li> <li>Categorical indicator kriging has been utilised to define sub-domains in lodes with mixed grade populations to limit the spread of high-grade mineralisation.</li> <li>Dynamic anisotropy has been employed on lodes exhibiting excessive undulation.</li> <li>Boundary analysis has been conducted on key lodes indicating hard boundaries should be maintained across domain and sub-domain contacts.</li> <li>Statistical and visual measures are used to validate the accuracy of the estimation.</li> <li>Volume variance between the wireframe domains and block model domains are assessed.</li> <li>A visual inspection of input composites is compared to the estimated block model in section for each domain.</li> <li>The mean grade of the block model is compared to the naïve and declustered mean grades of the composites by domain with any variance greater than 10% investigated.</li> <li>Swath plots are created by domain and sub-domain in the X, Y, Z, strike and cross strike directions and viewed holistically to vector into any problematic areas.</li> <li>Kriging efficiency, and slope results are reviewed by domain/sub-domain to give an indication of the quality of the estimate.</li> <li>Global change of support plots are created and reviewed for principal domains.</li> </ul> |

The Mineral Resource estimate was completed by Genesis Minerals Limited using Ordinary Kriging within 0.3g/t Au wireframes. High-grade shoots were modelled separately. The resource is reported above 0.4g/t Au (open pit) and 2.0g/t Au (underground). Metallurgical test work confirms gold recoveries of 88-91% via cyanide leaching.</li> <li>The Mineral Resources are reported inclusive of the Ore Reserve</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

The costs have been based on estimated drilling requirements and recent underground diamond drilling rates.</li><li>Mineral Resources used for optimisation were those detailed previously.</li><li>A cut-off grade of 1.7g/t was applied as the basis for initial stope design, with all designs assessed by detailed financial analysis to confirm their viability in consideration to the works required to access and extract them. The assessed designs were used to determine the economic extent of the orebody.</li><li>A cut-off grade of 0.81g/t was applied to development activities within the economic extent of the orebody as defined above,</li><li>A 10% dilution factor was applied to capital mine development (i.e. declines, level accesses and associated development) at zero grade.</li><li>Dilution was applied to operating mine development (i.e. ore drives) through increasing the planned cross sectional area of the design by 9%, then interrogating against the block model.</li><li>Stope dilution was included in optimisation shapes at a 1.15m depth of overbreak, reflecting geotechnical recommendations for dilution. The skin represents dilution of approximately 25% on the average width stopes at Ulysses.</li><li>In situ stope recovery as assumed at 90% after exclusion of rib and sill pillars from stope designs.</li><li>A minimum mining width of 2.5m was applied to underground stopes.</li><li>Inferred Resources were included in initial stope optimisation processes, however any Inferred material contained within final underground designs was treated as waste at zero grade.</li><li>The Project currently has mine offices, workshops, power, reverse osmosis, and wastewater treatment plants. Ore will be hauled using road trains to the existing Laverton and Gwalia processing plant</li></ul> |            |       |                             |                                         |
| Metallurgical Factors or Assumptions | <ul style="list-style-type: none"><li>The metallurgical process proposed and the appropriateness of that process to the style of mineralisation.</li><li>Whether the metallurgical process is well-tested technology or novel in nature.</li><li>The nature, amount and representativeness of metallurgical test work undertaken, the nature of the metallurgical domaining applied and the corresponding metallurgical recovery factors applied.</li><li>Any assumptions or allowances made for deleterious elements.</li><li>The existence of any bulk sample or pilot scale test work and the degree to which such samples are considered representative of the orebody as a whole.</li><li>For minerals that are defined by a specification, has the ore reserve estimation been based on the appropriate mineralogy to meet the specifications?</li></ul> | <ul style="list-style-type: none"><li>A primary crusher, SAG and ball mill circuit with a pebble crusher will produce a final grind size distribution P80 of 90 microns to be fed to a Carbon-In-Leach (CIL) circuit based on free milling nature of orebody based on metallurgical testwork.</li><li>Ore will be processed through the existing Gwalia processing facility located 35km North of Ulysses. This is a standard CIL circuit suitable for treatment of the Ulysses Ore</li><li>All underground Material is Fresh.</li><li>CIL is a standard and common gold extraction process for free milling ore.</li><li>Metallurgical recovery has been determined from Feasibility Study test work used to create a recovery model for Ulysses ore. The model determines the tailings grade and then uses the head grade to calculate recovery. The model was developed from 17 composites tested during the Feasibility study. The model is as shown in the table below, where [Au] is the gold head grade ing/t.</li><li>The recovery model for primary ore at Ulysses has a positive correlation between gold head grade and recovery.</li></ul> <table><tr><th>Ore Source</th><th>Model</th></tr><tr><td>Ulysses Underground Primary</td><td><math display="block">([Au] - (0.102[Au] + 0.045))/[Au]*100</math></td></tr></table> <ul style="list-style-type: none"><li>No deleterious elements were identified from the mineralogical/metallurgical assessments that impact on process selection.</li><li>The Ore Reserve has been estimated based on appropriate mineralogy to meet specifications from the Feasibility Study level testwork.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Ore Source | Model | Ulysses Underground Primary | $([Au] - (0.102[Au] + 0.045))/[Au]*100$ |

| Criteria                   | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sampling Techniques</b> | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual</li> </ul> | <ul style="list-style-type: none"> <li>The Admiral Group Resource is based on 1,846 RC and 52 diamond drill holes for a total of 118,125m</li> <li>In addition, a large amount of regional RAB (Rotary Air Blast) and air-core (AC) drilling has been completed at all prospects.</li> <li>Multiple campaigns of drilling were completed at each of the deposits by various explorers since 1985.</li> <li>Genesis RC and diamond drilling has included infill and extensional drilling.</li> <li>In the deposit areas, holes were generally angled at -60° to optimally intersect the mineralised zones.</li> <li>Genesis RC sampling in mineralised zones comprised 1m samples collected during drilling using a rig mounted cone splitter.</li> <li>Diamond core was cut using a diamond saw and sampled either at 1m intervals or to geological boundaries.</li> <li>RC and diamond drilling by previous holders has been completed to industry standard at the time.</li> </ul> |

| <b>techniques</b>                           | <p>interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</p> <ul style="list-style-type: none"> <li>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</li> <li>The assumptions made regarding recovery of by-products.</li> <li>Estimation of deleterious elements or other non-grade variables of economic significance (e.g., sulphur for acid mine drainage characterization).</li> <li>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</li> <li>Any assumptions behind modelling of selective mining units.</li> <li>Any assumptions about correlation between variables.</li> <li>Description of how the geological interpretation was used to control the resource estimates.</li> <li>Discussion of basis for using or not using grade cutting or capping.</li> <li>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</li> </ul> | <ul style="list-style-type: none"> <li>Leapfrog Geo software was used for geological interpretation and Datamine RM for estimation. Datamine's Snowden Supervisor was used to undertake geostatistical reviews.</li> <li>A single block model is used for all the deposits to facilitate a single optimisation.</li> <li>Samples were composited to 1m intervals and top cuts applied after a statistical review. The top-cut process affects only 1-2% of the data.</li> <li>The parent block cell size is set appropriate for the data density of the deposit. Sub-celling is permitted down to 1mX by 1mY by 1mZ to reflect volume fill.</li> <li>Previous resource estimates have been completed. The mineralisation domains used in this estimate were largely based on those previous interpretations and revised based on field mapping and new data collection.</li> <li>No assumptions have been made regarding recovery of by-products.</li> <li>No estimation of deleterious elements was carried out. Only Au was interpolated into the block models.</li> <li>An orientated ellipsoid search was used to select data and was based on kriging parameters, drill hole spacing and geometry of mineralisation. The estimation uses dynamic anisotropy to allow for local variation in dip/dip direction of the wireframes.</li> <li>Up to three interpolation passes were used for each model.</li> <li>A first pass search is modelled to the full length of the modelled variogram and uses a minimum of 8 samples and a maximum of 16 samples. Most blocks were estimated in the first pass.</li> <li>The remaining blocks were filled using an expanding search strategy. The second search expanded by 2 times, with the final search intended to fill the remaining un-estimated blocks in extrapolated areas.</li> <li>Selective mining units were not modelled in the Mineral Resource model. The block size used in the model was based on drill sample spacing and lode orientation; the block model is re-blocked prior to optimisation.</li> <li>The deposit mineralisation was constrained by wireframes constructed using a 0.25-0.3g/t Au-off grade. The wireframes were applied as hard boundaries in the estimates.</li> <li>For validation, trend analysis was completed by comparing the interpolated blocks to the sample composite data within strike intervals of 20m and by 10m vertical intervals and on a global basis.</li> </ul> |

The Laverton process plant was commissioned in late March 2018 and includes a Semi-Autogenous Grinding, Ball Milling and Pebble Crushing (SABC) comminution circuit followed by conventional gravity and carbon-in-leach (CIL) process. The Gwalia process plant consists of a 1.4 Mtpa crushing and grinding circuit followed by a conventional gravity recovery and carbon-in-leach (CIL) circuit.</li> <li>The metallurgical process is commonly used in Western Australian and international gold mining.</li> <li>A series of metallurgical test work programs have been undertaken for the Admiral Group deposit and used as the basis for determining the milling recovery factors for each pit. Domains were established by zone (Admiral, Butterfly, Butterfly North, Clark, Danluce, King) and by weathering state (oxide, fresh). All metallurgical test work programs were conducted on representative mineralised composites prepared from either RC chips or diamond drill core.</li> <li>There are no known deleterious elements, and no allowance is made in the Ore Reserve estimate for deleterious elements.</li> <li>The average recoveries for the Admiral Group domains are as follows: <table border="1"> <thead> <tr> <th></th><th>Laverton 106µm</th><th>Gwalia 90µm</th></tr> </thead> <tbody> <tr> <td>Admiral</td><td>89.6%</td><td>90.6%</td></tr> <tr> <td>Butterfly</td><td>87.6%</td><td>88.6%</td></tr> <tr> <td>Clark</td><td>90.1%</td><td>90.2%</td></tr> <tr> <td>Clark North</td><td>88.1%</td><td>89.3%</td></tr> <tr> <td>King</td><td>88.7%</td><td>89.7%</td></tr> </tbody> </table> </li> <li>No bulk sample test work has been carried out. Ore from the Admiral Group pits will be blended with other ore sources at the Laverton and Gwalia processing plants. Admiral, Butterfly, and King pits were previously mined in the 1990s. Ore from Admiral group is currently being processed at the Gwalia processing facility, however it is a small part of a</li> </ul>                                                                                                                                                                               |  | Laverton 106µm | Gwalia 90µm | Admiral | 89.6% | 90.6% | Butterfly | 87.6% | 88.6% | Clark | 90.1% | 90.2% | Clark North | 88.1% | 89.3% | King | 88.7% | 89.7% |

This data is forwarded to the Database Administrator for entry into a secure Datashed database with inbuilt validation functions.</li> <li>Data from previous owners was taken from a database compilation and validated as much as practicable before entry into the Genesis Datashed database.</li> <li>No adjustments have been made to assay data. First gold assay is utilised for resource estimation. Non positive values have been set to half lower detection limit (0.005 ppm).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Location of data points</b>                                 | <ul style="list-style-type: none"> <li>Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.</li> <li>Specification of the grid system used.</li> <li>Quality and adequacy of topographic control.</li> </ul>                                                                                              | <ul style="list-style-type: none"> <li>All drillhole collar locations are determined by DGPS and hence within 5 cm accuracy.</li> <li>Hub collar locations were completed using DGPS</li> <li>For NTM/DCN drilling the drill rig mast was set up using a clinometer and rig is orientated using handheld compass. Downhole surveys were conducted by a downhole gyro and measurements taken at varying intervals of approximately every 5 m to 50 m.</li> <li>For historical drilling, downhole surveys were conducted using methods that are not fully documented, with some holes relying solely on collar azimuth readings. This introduces potential uncertainty in the spatial positioning of historical drillholes, particularly in deeper sections of the deposit. Where feasible, recent drilling has been used to verify historical hole positions, and adjustments have been made to collar RLs based on DGPS data to improve spatial accuracy. Despite these measures, areas relying predominantly on historical drill data have been assigned a lower confidence classification.</li> <li>Some historic collar RL positions were adjusted to reflect more recent and more accurate pickups by DGPS.</li> </ul> |
| <b>Data spacing and distribution</b>                           | <ul style="list-style-type: none"> <li>Data spacing for reporting of Exploration Results.</li> <li>Whether the data spacing, and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.</li> <li>Whether sample compositing has been applied.</li> </ul>                                | <ul style="list-style-type: none"> <li>Grid projection is GDA94, Zone 51.</li> <li>A DTM has been created for the Hub Gold Project based on all available DGPS data, with an accuracy of 5 cm. Relative Levels have been assigned based on this DTM.</li> <li>Drill spacing is on an approximate 25 m grid which extends to 50 m in some areas. Grade Control (GC) drilling has been completed on a 12m x 6m drill spacing</li> <li>The resource classification reflects the level of confidence reached when considering drillhole spacing, confidence in geological interpretation, QA/QC and the amount of historical drilling.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Orientation of data in relation to geological structure</b> | <ul style="list-style-type: none"> <li>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</li> <li>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</li> </ul> | <ul style="list-style-type: none"> <li>The vast majority the drilling is orientated perpendicular to the strike of the individual deposits. Also, much of the drilling intersects the mineralisation at high angles resulting in close to true widths being generated.</li> <li>The drill hole azimuths and dips are generally perpendicular to the mineralisation and hence should not introduce any sampling bias.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Several minor subsidiary hanging and footwall lodes are present. The main lode has been cut by late dolerite and lamprophyre dykes which offset and disrupt the mineralisation in places. The depth of complete oxidation varies from between 50 and 100m below surface which is underlain by a transitional horizon typically 25m thick to the top of fresh horizon. A thin laterite cap covers the deposit.</li> </ul> |

|                                             | <ul style="list-style-type: none"> <li>• <i>Estimation of deleterious elements or other non-grade variables of economic significance (e.g., sulphur for acid mine drainage characterization).</i></li> <li>• <i>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</i></li> <li>• <i>Any assumptions behind modelling of selective mining units.</i></li> <li>• <i>Any assumptions about correlation between variables.</i></li> <li>• <i>Description of how the geological interpretation was used to control the resource estimates.</i></li> <li>• <i>Discussion of basis for using or not using grade cutting or capping.</i></li> <li>• <i>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</i></li> </ul> | <p>maximum distance of extrapolation from last known data points for the inferred material is dependent on the geological continuity and confidence across the lode, but less than 80m for the deposit.</p> <ul style="list-style-type: none"> <li>• Search distances are dictated by the range of each individual variogram. A 3-pass nested search strategy is employed with the first pass always set to the full range of the variogram. The second pass is set at 2 times the variogram range with the final pass set at a factor large enough to ensure all blocks comprising the domain are estimated.</li> <li>• The Mineral Resource Estimation is checked against the previous block model estimations following any material update.</li> <li>• No assumptions are made regarding the recovery of by-products for this Mineral Resource Estimation.</li> <li>• No estimation of deleterious elements or non-grade variables is required.</li> <li>• No assumptions have been made regarding the modelling of selective mining units for this Mineral Resource Estimation</li> <li>• No assumptions have been made regarding the correlation between variables for this Mineral Resource Estimation.</li> <li>• Mineralisation is partitioned into estimation domains relative to stratigraphic position, structural orientation, recorded lithology and specific alteration assemblage. The geological interpretation is initially created from drill data and later calibrated with mapping from open pit exposures.</li> <li>• Domains are estimated individually with search geometry and variography controlled by lode orientation and grade continuity respectively. Variogram major search directions are aligned with geologically interpreted high grade shoot trends.</li> <li>• Dynamic anisotropy has been employed on lodes exhibiting excessive undulation.</li> <li>• Boundary analysis has been conducted on key lodes indicating hard boundaries should be maintained across domain contacts.</li> <li>• Statistical and visual measures are used to validate the accuracy of the estimation.</li> <li>• Volume variance between the wireframe domains and block model domains are assessed.</li> <li>• A visual inspection of input composites is compared to the estimated block model in section for each domain.</li> <li>• The mean grade of the block model is compared to the naïve and declustered mean grades of the composites by domain with any variance greater than 10% investigated.</li> <li>• Swath plots are created by domain and sub-domain in the X, Y, Z, strike and cross strike directions and viewed holistically to vector into any problematic areas.</li> <li>• Kriging efficiency, and slope results are reviewed by domain to give an indication of the quality of the estimate.</li> <li>• Global change of support plots are created and reviewed for principal domains.</li> </ul> |

It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider the potential environmental impacts of the mining and processing operation. While at this stage the determination of potential environmental impacts, particularly for a greenfields project, may not always be well advanced, the status of early consideration of these potential environmental impacts should be reported. Where these aspects have not been considered this should be reported with an explanation of the environmental assumptions made.</li> </ul>                                                                                                                                                                                         | <ul style="list-style-type: none"> <li>It is considered that there are no significant environmental factors, which would prevent the eventual extraction of material.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Sampling Techniques</b> | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3kg was pulverised to produce a 30g charge for fire</li> </ul> | <ul style="list-style-type: none"> <li>Surface and underground diamond core is NQ (50.6mm) sized core, sampled to 1m intervals or geological boundaries where necessary and cut into half core. The upper or right-hand side of the core is routinely submitted for sample analysis, with each one metre of half core providing between 2.5 – 3kg of material as an assay sample. Minimum sample length is 0.30m for DD core.</li> <li>RC chips are cone or riffle split and sampled into 1m intervals.</li> <li>All sampling methods are used to produce representative sample of less than 3kg. Samples are selected to weigh less than 3kg to ensure total sample inclusion at the pulverisation stage.</li> <li>Genesis core and chip samples are crushed, dried and pulverised to a nominal 90% passing 75µm to produce a 40g or 50g sub sample for analysis by FA/AAS.</li> <li>Historical AC, RAB, RC and diamond sampling was carried out to industry standard at that time. Analysis methods include fire assay and unspecified methods.</li> </ul> |

| Criteria                                              | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                       | <p>assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

The material mined incorporates stacked, gently east-dipping mafic lodes, syenite stocks, and felsic porphyry intrusives.</li> <li>The Jupiter deposit is interpreted to comprise structurally controlled mesothermal gold mineralisation related to syenite intrusions within altered basalt. Most mineralisation is associated with large, shallow, east-dipping shears, most significantly developed where these shears crosscut syenite intrusions or the altered basalt proximal to the syenite intrusions. Within and partially projecting only a short distance out of the Joanne syenite pipe, three carbonatite dykes have been modelled. These are weakly mineralised compared with the Joanne syenite pipe.</li> <li>On the north side of the Heffernans pipe, a skin-like syenite dyke or radial intrusion has formed with a distinct, relatively consistent band of sericite-hematite-altered basalt separating it from the main pipe by approximately 5m – 10m.</li> <li>A deposit-scale, shallow east-dipping structure known as the Cornwall Shear Zone (CSZ) transects all geology, which is most highly mineralised in its intersection of the major syenite pipes. Although the tenor decreases distally from the syenite pipes, the CSZ still presents itself as a higher-grade feature and mineralisation target. Several CSZ-parallel mineralisation lodes in the hanging wall above the CSZ have been mined with some success, although these are largely depleted through mining. The CSZ is clearly defined in the Joanne, Jenny, and Heffernans pipes, and through some Saddle Zone dykes, but becomes gradually less distinct elsewhere, with no clear boundary to its extents.</li> </ul> |

|                                      | <p>points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</p> <ul style="list-style-type: none"> <li>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</li> <li>The assumptions made regarding recovery of by-products.</li> <li>Estimation of deleterious elements or other non-grade variables of economic significance (e.g., sulphur for acid mine drainage characterization).</li> <li>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</li> <li>Any assumptions behind modelling of selective mining units.</li> <li>Any assumptions about correlation between variables.</li> <li>Description of how the geological interpretation was used to control the resource estimates.</li> <li>Discussion of basis for using or not using grade cutting or capping.</li> <li>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</li> </ul> | <ul style="list-style-type: none"> <li>Lode wireframes are intersected with a validated drill database from which all RAB, air core, and erroneous drill holes have been removed. All remaining diamond and RC samples are flagged with a domain identifier and composited to 1m with 0.3m minimum sample. Residual samples are distributed across adjacent component intervals.</li> <li>Composites are analysed for population outliers by domain and are topcut proximal to population disintegration. The top-cut process affects only 1-2% of the data.</li> <li>Grade tenure for mineralisation that crosses lithological boundaries has undergone a contact analysis, particularly the CSZ within basalt and syenite host lithologies. Contact analysis has shown that a soft boundary is appropriate for estimation across the syenite contact.</li> <li>The one-way soft boundary that has been implemented works whereby the CSZ inside the syenites and basalts are estimated independently, however samples inside the syenite can see samples in the basalt up to 5m (distance determined by contact analysis)</li> <li>Variography is created for all domains with sufficient sample data. Output variograms are utilised in kriging neighbourhood analysis (KNA) to generate optimum parent block sizes and estimation parameters.</li> <li>Domains are estimated using ordinary kriging utilising the estimation parameters defined in the KNA as inputs. Grade is estimated into parent blocks only and all kriging quality metrics and search pass values are output. The maximum distance of extrapolation from last known data points for the inferred material is dependent on the geological continuity and confidence across the lode, but less than 80m for the deposit.</li> <li>Search distances are dictated by the range of each individual variogram but typically equate to 1-2 times the current 20x20m resource definition spacing. A 3-pass nested search strategy is employed with the first pass always set to the full range of the variogram. The second pass is set at 2 times the variogram range with the final pass set at a factor large enough to ensure all blocks comprising the domain are estimated.</li> <li>The Mineral Resource Estimation is checked against the previous block model estimations following any material update.</li> <li>No assumptions are made regarding the recovery of by-products for this Mineral Resource Estimation.</li> <li>No estimation of deleterious elements or non-grade variables is required.</li> <li>No assumptions have been made regarding the modelling of selective mining units for this Mineral Resource Estimation</li> <li>No assumptions have been made regarding the correlation between variables for this Mineral Resource Estimation.</li> <li>Mineralisation is partitioned into estimation domains relative to stratigraphic position, structural orientation, recorded lithology and specific alteration assemblage. The geological interpretation is initially created from drill data and later calibrated with mapping from open pit exposures.</li> <li>Domains are estimated individually with search geometry and variography controlled by lode orientation and grade continuity respectively. Variogram major search directions are aligned with geologically interpreted high grade shoot trends.</li> <li>Dynamic anisotropy has been employed on lodes exhibiting excessive undulation.</li> <li>Statistical and visual measures are used to validate the accuracy of the estimation.</li> <li>Volume variance between the wireframe domains and block model domains are assessed.</li> <li>A visual inspection of input composites is compared to the estimated block model in section for each domain.</li> <li>The mean grade of the block model is compared to the naïve and declustered mean grades of the composites by domain with any variance greater than 10% investigated.</li> <li>Swath plots are created by domain and sub-domain in the X, Y, Z, strike and cross strike directions and viewed holistically to vector into any problematic areas.</li> <li>Kriging efficiency, and slope results are reviewed by domain to give an indication of the quality of the estimate.</li> <li>Global change of support plots are created and reviewed for principal domains.</li> </ul> |

The Mineral Resource estimate for Jupiter was completed using Ordinary Kriging on 1m composites within wireframes at a 0.4g/t Au cut-off. The resource is classified under JORC (2012) guidelines as Measured, Indicated, and Inferred. Metallurgical recoveries from previous mining (2017-2022) averaged 91%.</li> <li>The Mineral Resources are reported inclusive of the Ore Reserve.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Environmental                        | <ul style="list-style-type: none"><li>The status of studies of potential environmental impacts of the mining and processing operation. Details of waste rock characterisation and the consideration of potential sites, status of design options considered and, where applicable, the status of approvals for process residue storage and waste dumps should be reported.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <ul style="list-style-type: none"><li>All regulatory approvals and permits have been granted for ongoing mining and processing at Laverton, including mining of the Jupiter Mining Area. This includes approvals for extensions to the TSF and water sourced from a combination of the current pit workings and the licensed Laverton bore field. An addendum to the mining proposal is required to cover the planned extension to the pit. At this stage there are no known reasons to believe that this additional approval will not be approved on time and prior to mining commencing.</li><li>Waste rock characterisation was completed on drill samples as a component of the 2016 DFS. All Jupiter waste rocks were characterised as non-acid forming (NAF) apart from highly localised portions of basalt and to a lesser extent, intermediate quartz porohrvr. This material accounts for less than 6% of all waste rock mined from the Jupiter pits.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                      |      |                             |              |                                          |      |      |

Mineralisation is associated with basalt hosted shearing and sheared intrusive contacts. Mineralised intervals typically display a combination of chlorite-carbonate to sericite-albite alteration with increased fine disseminated sulphide (predominantly pyrite with lesser chalcopyrite).</li> <li>Mineralisation within felsic rock intrusions is associated with quartz-carbonate veining with pyrite-chalcopyrite, and disseminated pyrite-chalcopyrite adjacent to the veins as a selvage. Mineralisation and host rocks within the nearby open pit confirm the geometry of the mineralisation.</li> <li>There are both visual and non-visual mineralisation types at Mt Marven. Some mineralized shear zones are clearly visible within pit exposures and in drill chips, distinguished by goethitic to hematitic red defined zones that correlate with grades greater than 0.3g/t Au. Beneath the oxidized profile, higher gold grades are sometimes associated with higher disseminated pyrite and sometimes associated with silica-sericite +/- albite alteration.</li> </ul> |

There are a series of lode structures striking north and dipping at 60° – 75° to the east, shallowing in the east. Mineralised shear zones can be hematite altered in the oxide material and sericite/carbonate altered in fresh rock.</li> <li>The mineralisation was modelled with a relatively strict gold cut-off of 0.3g/t Au, which has been confirmed as appropriate for the mining methods and ore markouts.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Estimation and modelling techniques</b> | <ul style="list-style-type: none"> <li>• <i>The nature and appropriateness of the estimation technique(s) applied and key assumptions, including treatment of extreme grade values, domaining, interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</i></li> </ul> | <ul style="list-style-type: none"> <li>• Samples were composited to 1m intervals ("composites") based on assessment of the raw drillhole sample intervals. Statistics were weighted by composite length in Supervisor.</li> <li>• High-grade top-cuts ranging from 4.9 – 20g/t Au were applied to the mineralisation domains following statistical analysis completed in Snowden Supervisor™ software.</li> <li>• The top-cuts were kept at around 1% – 2% of the grade distribution for each lode.</li> <li>• To model the spatial continuity of gold grades, variography was conducted in Supervisor 8.12. Statistics were length-weighted.</li> <li>• Composite samples were declustered prior to variography for the statistical domains that contained lodes. A normal-score transform was applied to all data.</li> <li>• In total, there are 62 individual mineralized lodes at Mt Marven. Due to lack of data in some lodes, they were grouped together based on lode orientation, statistics and location. The groups consist of the following: <ul style="list-style-type: none"> <li>○ Supergene envelope</li> <li>○ NNW-SSE lodes in north-western pit area</li> <li>○ NNW-SSE lodes in southern area</li> <li>○ N-S lodes in southern area</li> <li>○ NW-SE lodes in southern area</li> <li>○ Lode 6 – WNW structure splitting north and south pit</li> <li>○ Lode 25 – large, flat EW lode at northern end</li> </ul> </li> <li>• Variograms were modelled for each of the above lode groups – seven in total. The majority of the variograms yielded poor experimental variograms, however, the modelling of short-range and long-range spherical structures was possible.</li> <li>• Two spherical structures were modelled for each lode group.</li> <li>• After variograms were modelled, a back-transform model was exported with Datamine rotations for use in Datamine parameter files. All variograms contained a low nugget when back-transformed, and typically a very high proportion of the variance accounted for in the short-range structure.</li> <li>• Multi-block kriging neighbourhood analysis (KNA) was undertaken using Supervisor™ software to assess the effect of changing key kriging neighbourhood parameters on block grade estimates. Kriging efficiency (KE), slope of regression (SOR) and negative weights were determined for a range of block sizes, minimum and maximum samples, search dimensions and discretisation grids.</li> <li>• KNA found that a 5 x 5 x 5m block size was among the best statistics, and was considered most appropriate considering the drill density. KNA suggested using between 6 and 8 minimum samples and between 16 and 20 maximum samples. The maximum samples allowed per drillhole was set to 3 for all lodes. These parameters were set for the first pass.</li> <li>• The KNA suggested adopting a search ellipse size matching the short-range structure in all cases, followed by the full range. The short range structure was often very short (6m to 28m in the major directions.)</li> <li>• The second pass was the full range of the variogram, from 16.8m to 57.6 m, and the minimum samples was 10 and maximum was 20. The third pass was 8x to 12x the full range of the variogram, from 60m to 224 m, and the minimum samples was 4 and maximum was 8.</li> <li>• The major direction was modelled with a ratio of between 1.2x to 2.3x the semi-major direction, and 2.3x 6.8x the minor direction. The latter of 6.8x ratio to the minor is an exception, relating to domain South, which incorporates</li> </ul> |

|                           |                                                                                                                                                                                        | <p>variogram orthogonally, except for the first pass, which employed dynamic anisotropy (DA), and the dynamic orientation of the search ellipse in Surpac causes the major and semimajor directions to be incorrect. DA was employed as local flexures not related to modelled structural offsets (which divided the deposit's modelled objects) were evident.</p> <ul style="list-style-type: none"> <li>Search parameters for each pass were as follows: <ul style="list-style-type: none"> <li>Pass 1: <ul style="list-style-type: none"> <li>Search ellipse size 44 m, isotropic in the major-semimajor plane, DA</li> <li>Minimum samples: 9</li> <li>Maximum samples: 22</li> <li>Maximum samples per hole: 6</li> <li>Discretisation: 3 by 3 by 3</li> </ul> </li> <li>Pass 2: <ul style="list-style-type: none"> <li>Search ellipse size 100% of the full range of the domain variogram (44m to 118 m)</li> <li>Minimum samples: 9</li> <li>Maximum samples: 22</li> <li>Maximum samples per hole: 6</li> <li>Discretisation: 3 by 3 by 3</li> </ul> </li> <li>Pass 3: <ul style="list-style-type: none"> <li>Search ellipse size 300 m</li> <li>Minimum samples: 4</li> <li>Maximum samples: 10</li> <li>Maximum samples per hole: 6</li> <li>Discretisation: 3 by 3 by 3</li> </ul> </li> </ul> </li> <li>Grades have not been interpolated into the waste, as there is little evidence for a grade halo or mineralisation in other objects.</li> <li>In 2019, Dacian Gold updated the MRE following the receipt of data from 37 RC holes for a total length of 2,900m drilled during 2019</li> <li>The deposit has not been mined; therefore, no production data is available.</li> <li>No assumptions have been made regarding the recovery of by-products.</li> <li>No deleterious elements have been estimated.</li> <li>A parent block size of 15m x 15m x 10m (X x Y x Z) was chosen, which was supported KNA and by drill hole spacing all directions.</li> <li>Sub-celling to 1/8 of parent cell in all directions has provided appropriate resolution for volume control to account for the moderately thin lode wireframes.</li> <li>Most of the deposit has been drilled at a density of 20m by 20m and out to 40m by 40m on the fringes.</li> <li>No assumptions have been made regarding SMUs.</li> <li>Gold has been estimated univariately and in isolation of other variables.</li> <li>Geology and grade were used to define the mineralisation lodes. Within each lode, the estimate was constrained to blocks within the lode wireframe using only top-cut composited samples from the corresponding lode.</li> <li>High-grade top-caps were applied to limit the influence of extreme outliers on the grade estimate. The top-caps were applied to the mineralisation domains following statistical analysis.</li> <li>The top-cuts were kept at around 1% – 2% of the distribution.</li> <li>Validation of the estimate was completed for the resource block models using numerical methods (histograms, CDFs and swath plots) and validated visually against the input raw drillhole data, declustered data, composites and blocks.</li> </ul> |

All are intercalated within or separated by ultramafic volcanic rocks and variably intruded by felsic porphyry dykes and lamprophyres. Gold mineralisation is associated with quartz carbonate fractures and fine veinlets within BIF. BIF acts as the primary host for mineralisation though other rock types including basalt, porphyry intrusive and ultramafic may also be mineralised in smaller volumes and with less continuity. The grade and geometry of mineralisation is controlled by cross cutting structures that are interpreted to introduce reduced fluids into the oxidised BIF host.</li> </ul> |

| <b>Database integrity</b>        | <ul style="list-style-type: none"> <li>Measures taken to ensure that data has not been corrupted by, for example, transcription or keying errors, between its initial collection and its use for Mineral Resource estimation purposes.</li> <li>Data validation procedures used.</li> </ul> | <ul style="list-style-type: none"> <li>Ongoing DB validation undertaken by dedicated DB admin communicating with geologists as the primary data sources and labs. Extensive validation undertaken by the database administrator. Data loaded into DataShed with back-end SQL Server DB on a related data schema, providing a referentially integral database with primary key relations and look-up validation fields.</li> <li>Additional validation completed Surpac by Dacian geologists, with any validation issues relayed to DB administrator.</li> <li>All data were checked for the following errors: <ul style="list-style-type: none"> <li>Duplicate drillhole IDs</li> <li>Missing collar coordinates</li> <li>Mis-matched or missing FROM or TO fields in the interval tables (assays, logging etc)</li> <li>FROM value greater than TO value in interval tables</li> <li>Non-contiguous sampling intervals</li> <li>Sampling interval overlap in the assay table</li> <li>The first sample in the interval file not starting at 0 m</li> <li>Interval tables with depths greater than the collar table EOH depth.</li> <li>Survey data were checked for large deviations in azimuth and dip between consecutive records, with none found.</li> </ul> </li> </ul>                                                                                                                                                                   |
| <b>Site visits</b>               | <ul style="list-style-type: none"> <li>Comment on any site visits undertaken by the Competent Person and the outcome of those visits.</li> <li>If no site visits have been undertaken indicate why this is the case.</li> </ul>                                                             | <ul style="list-style-type: none"> <li>The Competent Person has not visited McKenzie Well, but has made several visits to the Laverton area, including the same BIF stratigraphy that hosts the Westralia Area deposits. The Competent Person relied on colleagues for their knowledge and guidance in the preparation of the MRE, and has reviewed the drilling and sampling practices for the same drilling contractor as the RCdrilling campaign that sampled the deposit for Dacian Gold.</li> <li>The Competent Person has not visited Bureau Veritas, the laboratory in Kalgoorlie, that undertook the assaying for Dacian samples.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Geological interpretation</b> | <ul style="list-style-type: none"> <li>Confidence in (or conversely, the uncertainty of ) the geological interpretation of the mineral deposit.</li> <li>Nature of the data used and of any assumptions made.</li> </ul>                                                                    | <ul style="list-style-type: none"> <li>The confidence in the geological model is moderately high. The BIF stratigraphy conforms well to the nominal mineralisation modelling cut-off of 0.3g/t Au. Geological mapping of the BIF outcrops was used to guide the surface extension of the mineralisation wireframe interpretations. The mapping and wireframes broadly showed high correlation. Geological logging was informed by strong knowledge of the Westralia stratigraphy, in which the resources are located.</li> <li>Detailed geological/alteration/structural logging in conjunction with chemical assays have been used during the interpretation process to minimise assumptions and risk.</li> <li>The DGPS collar pick-ups in 2019 of the pegs of the 17 historic drillholes completed in 1988 ("MWRC1" through "MWRC19"), and which informed the Mineral Resource estimate, are assumed to be in the original positions of the collars without significant movement. Although it is possible that the pegs may have moved to a significant degree, these historic holes have been infilled to a high degree by the density of recent 2020 drilling by Dacian Gold (90 holes), meaning that the Mineral Resource estimate does not rely on any clusters of historic holes. Although no holes have been twinned, the mineralisation intercepts between the historic and recent drilling shows good visual correlation.</li> </ul> |

Wireframes have been constructed for the host BIF mineralisation as determined by the geological logging and chemical assays. <i>The Mineral Resources are hosted within two banded iron formation limbs of an overturned, south plunging syncline with vergence to the SSE at the fold hinge, where several axial planar lodes have developed. The geological model of the banded iron formation (BIF) forms the basis of the mineralisation model, as the two showed high visual correlation. The wireframes of BIF encompass 10 lodes of mineralisation, lodes 1 through 5 lying on the western-most Viper Tooth limb, and lodes 6 through 10 lying on the eastern-most Welshgreen limb. The lodes were used to select and composite samples as hard-boundaries, determine statistics, and estimate grades by each individual lode by the corresponding composites within the lode.</i></li> <li>Following statistical analysis, two domains representing the lodes of the two limbs were created to group mineralisation lenses together. Composites were selected within the mineralisation discretely. The block model was coded with the wireframes and the MRE was conducted by constraining composites and blocks to each relevant domain</li> <li>Investigation of the geological logging was undertaken for the presence porphyry dykes that commonly deplete the mineralisation in the Westralia deposits, but only insignificant intercepts were identified, and no geological continuity was established.</li> </ul>                                                                                                                                                                                                                                                                                    |

|                                                       | <ul style="list-style-type: none"> <li>• Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>• Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>• Dacian RC holes were sampled over the entire length of hole.</li> <li>• Dacian RC drilling was sampled at 1m intervals via an on-board cone splitter.</li> <li>• Dacian RC drilling was sampled on 1m intervals via an on-board cone splitter to achieve approximately 3kg samples, and then samples were dried in laboratories.</li> <li>• For fire assay and ICPES, samples were submitted to a contract laboratory. After drying, the sample was subject to a primary crush, then pulverised to 85% passing 75µm to produce either a 40g or 50g. Sample preparation was conducted by a contract, National Association of Testing Authorities (NATA) Australia accredited laboratory.</li> <li>• For samples analysed by PAL, dried samples were subjected to a primary and secondary crush to 90% passing 3 mm, before being cone split into a 600g subsample. The 600g sample was then pulverised to 90% passing 80 µm and simultaneously leached for 60 minutes in a PAL machine using 2kg of grinding media, 1 Litre of water and 2 x 10g cyanide tablets (75% NaCN). The leached solution was separated by centrifuge and analysed by AAS.</li> </ul> |

Most samples were dry, any wet samples are recorded as wet, this data is then entered into the sample condition field in the drillhole database.</li> <li>• The RC sample was split using the cone splitter to give an approximate 3kg sample. The remainder was collected into a plastic sack as a retention sample. At the grain size of the RC chips, this method of splitting is considered appropriate.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The Dump-leach has remained in place since construction in 1994 and completion in 1996, followed by heap-leach processing. Therefore, there is uncertainty how much addition of moisture by rainfall and subsequent drying has taken place.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |       |             |       |      |         |                              |      |      |      |      |             |                               |      |      |      |      |             |                      |      |      |      |      |  |                  |      |      |      |      |  |                              |      |      |      |      |             |

It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider potential metallurgical methods, but the assumptions regarding metallurgical treatment processes and parameters made when reporting Mineral Resources may not always be rigorous. Where this is the case, this should be reported with an explanation of the basis of the metallurgical assumptions made.</li></ul>                                                                                                                                                       | <ul style="list-style-type: none"><li>In 2022, Dacian undertook metallurgical recovery testwork on four composite samples, which yielded a calculated assay mean gold grade of 0.34g/t and a recovery of 85.7%.</li><li>In 2020, metallurgical testwork by Dacian achieved a mean calculated head grade of 0.64g/t and an 80% recovery.</li><li>Metallurgical testwork summary for Dump-leach dump undertaken during 2022<table><tr><td>Composite name</td><td>HL 21</td><td>HL 28</td><td>HL 52</td><td>HL57</td><td>Average</td></tr><tr><td>Assay Values from Hole (g/t)</td><td>0.71</td><td>0.78</td><td>0.40</td><td>0.44</td><td><b>0.58</b></td></tr><tr><td>Recalculated Head Grade (g/t)</td><td>0.29</td><td>0.51</td><td>0.32</td><td>0.25</td><td><b>0.34</b></td></tr><tr><td>PAL Final Tail (g/t)</td><td>0.04</td><td>0.04</td><td>0.04</td><td>0.03</td><td></td></tr><tr><td>PAL Recovery (%)</td><td>87.9</td><td>92.1</td><td>87.4</td><td>88.1</td><td></td></tr><tr><td>Estimated Plant Recovery (%)</td><td>84.4</td><td>90.2</td><td>84.2</td><td>84.1</td><td><b>85.7</b></td></tr></table><ul style="list-style-type: none"><li>Note: PAL = pulp-and-leach method employing the Leachwell™ leaching process.</li></ul></li><li>The estimated plant recovery was based on 0.01g/t solution to tail, which may show lower solution losses for low-grade samples, hence slightly increased recovery.</li></ul> | Composite name | HL 21 | HL 28       | HL 52 | HL57 | Average | Assay Values from Hole (g/t) | 0.71 | 0.78 | 0.40 | 0.44 | <b>0.58</b> | Recalculated Head Grade (g/t) | 0.29 | 0.51 | 0.32 | 0.25 | <b>0.34</b> | PAL Final Tail (g/t) | 0.04 | 0.04 | 0.04 | 0.03 |  | PAL Recovery (%) | 87.9 | 92.1 | 87.4 | 88.1 |  | Estimated Plant Recovery (%) | 84.4 | 90.2 | 84.2 | 84.1 | <b>85.7</b> |

| <b>Environmental factors or assumptions</b> | <ul style="list-style-type: none"><li>Assumptions made regarding possible waste and process residue disposal options. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider the potential environmental impacts of the mining and processing operation. While at this stage the determination of potential environmental impacts, particularly for a greenfields project, may not always be well advanced, the status of early consideration of these potential environmental impacts should be reported. Where these aspects have not been considered this should be reported with an explanation of the environmental assumptions made.</li></ul> | <ul style="list-style-type: none"><li>The Dump Leach was rehabilitated, and therefore approval is required to allow its disturbance. It is assumed that there will be no impediment to mine the Dump Leach.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |       |             |       |      |         |                              |      |      |      |      |             |                               |      |      |      |      |             |                      |      |      |      |      |  |                  |      |      |      |      |  |                              |      |      |      |      |             |

| <b>Classification</b>                             | <ul style="list-style-type: none"> <li>The basis for the classification of the Mineral Resources into varying confidence categories.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                    | <ul style="list-style-type: none"> <li>The MRE has been classified based on the guidelines specified in The JORC Code. Classification level is based on: <ul style="list-style-type: none"> <li>Drill sample density data</li> <li>Geological understanding</li> <li>Quality of density samples</li> <li>Reliability of the density estimate</li> <li>Quality of gold assay grades</li> <li>Continuity of gold grades</li> <li>Economic potential for mining</li> </ul> </li> <li>The Mineral Resources have been classified as Inferred on the basis that the dump leach volume solely defines the geological model, meaning that the grade estimate has no further geological control. Therefore, despite the drill hole density reaching 10m by 10m for a significant proportion of the area, the estimate of grades and the recovery of metal cannot be defined on a locally accurate basis, and only a global grade is applicable. Therefore, Mineral Resources are only classified on the bases that the entire Dump-leach dump volume is mined and treated with no selectivity.</li> <li>Internal financial modelling by Dacian shows that the estimated grade may be economic once blended with other material. The Competent Person has established that RPEEE exists on the basis that there are enough grounds for Mineral Resource classification by reference to Clause 41 of the JORC Code: "If some portion of the mineralised material is currently sub-economic, but there is a reasonable expectation that it will become economic, then this material may be classified as a Mineral Resource."</li> <li>However, the uncertainty in the grade estimate from the sampling loss and proportion attributable to cavities, means that the inability to provide an accurate estimate of the tonnages and particularly the grade at such marginal financial modelling measures means that the confidence in the RPEEE is low. Therefore, the Dump Leach will remain Inferred until material can be batch treated to demonstrate RPEEE.</li> </ul> |

## JORC Table 1 Checklist of Assessment and Reporting Criteria

### Section 1 Sampling Techniques and Data – Cardinia Group

| Criteria                     | JORC Code explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sampling Techniques</b>   | <ul style="list-style-type: none"> <li>Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information.</li> </ul> | <ul style="list-style-type: none"> <li>Surface diamond core is NQ2 or HQ3 sized core, sampled to 1m intervals or geological boundaries where necessary and cut into half core or quarter core longitudinally. The upper or right-hand side of the core is routinely submitted for sample analysis, with each one metre of half core providing between 2.5 – 3kg of material as an assay sample. Minimum sample length is 0.30m for DD core. Some historical core is 0.2m in length.</li> <li>RC chips are cone or riffle split and sampled into 1m intervals.</li> <li>All sampling methods are used to produce representative sample of less than 3kg. Samples are selected to weigh less than 3kg to ensure total sample inclusion at the pulverisation stage.</li> <li>Genesis core and chip samples are crushed, dried and pulverised to a nominal 90% passing 75µm to produce a 40g or 50g sub sample for analysis by FA/AAS.</li> <li>Historical AC, RAB, RC and diamond sampling was carried out to industry standard at that time. Analysis methods include fire assay and unspecified methods. On occasion, initial assaying may have been carried out via Aqua Regia digest and AAS/ICP finish. Anomalous samples were subsequently re-assayed by Fire Assay fusion and AAS/ICP finish.</li> <li>Multi element analysis was also conducted on approximately 10% of samples, predominantly through ore zones. This was conducted via a 4-acid digest with ICP-MS/OES determination for a 48-element suite.</li> <li>All rock chip samples were taken using a pick. The samples are taken from outcrop where possible. Samples are also taken from in situ float material or waste rock around historic workings, where outcrop is not present. Care is taken to ensure all samples are representative of the medium being sampled. For example, if a 1m sediment unit is being sampled, a channel sample will be taken across the entire unit.</li> </ul> |
| <b>Drilling Techniques</b>   | <ul style="list-style-type: none"> <li>Drill type (e.g. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g. core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <ul style="list-style-type: none"> <li>Drill holes used in the estimate include 45 diamond holes (DDH), 5,502 reverse circulation holes and 3 diamond holes collared from surface have RC pre-collars (RCD). In addition, large number of regional RAB (Rotary Air Blast) and air-core (AC) holes have been completed but excluded from the estimation due to lower sample quality.</li> <li>DDH typically used NQ (45-48mm) and HQ (61-64mm) sized core (standard double tubes). Drill core is retrieved from the inner tubes and placed in plastic core trays and each core run depth recorded onto core marker blocks and placed at the end of each run in the tray.</li> <li>Core orientation was obtained for each core run where possible, using electronic core orientation tools (e.g. Reflex EZ-ACT) and the 'bottom of core' marked accordingly.</li> <li>Drill holes were down hole surveyed by either north seeking gyro within the rods or by electronic multi-shot in open holes. Independent programs of downhole deviation surveying were also carried out to validate previous surveys. These programs utilised either electronic continuous logging survey tool (AusLog A698 deviation tool) or gyroscopic survey equipment. Less than 10% of holes were surveyed down hole using a Reflex Single Shot camera.</li> <li>RC holes used mainly 5½" reverse circulation face sampling hammers.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Database integrity</b>        | <ul style="list-style-type: none"> <li><i>Measures taken to ensure that data has not been corrupted by, for example, transcription or keying errors, between its initial collection and its use for Mineral Resource estimation purposes.</i></li> <li><i>Data validation procedures used.</i></li> </ul>                                                                                                                                                                                                       | <ul style="list-style-type: none"> <li>The database used for the estimate is an extract from an Datashed SQL database. The primary database is regulated by a locked framework which fixes the relationships between tables. The data model minimises the potential for data collection and data usage errors through pre-determined look up tables, storage and export functions.</li> <li>User defined permissions also regulate the ability to add, edit or extract data.</li> <li>Primary data is recorded using typical manual translation of logging and data capture from written logs and direct import of csv tables through a data import scheme where data is validated upon import or direct data entry options into the database using predefined look up values.</li> <li>Data that is captured in the field is entered into Excel templates which are checked on import into the database for errors. Assay jobs are dispatched electronically to the lab to minimise the chance of data entry errors. Assay results from the lab are received in CSV format and are checked for errors on import into the database. Data is regularly validated using the mining software. The data validation process is overseen by the Database Administrator.</li> </ul> |

| <b>Estimation and modelling techniques</b> | <ul style="list-style-type: none"> <li>The nature and appropriateness of the estimation technique(s) applied and key assumptions, including treatment of extreme grade values, domaining, interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</li> <li>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</li> <li>The assumptions made regarding recovery of by-products.</li> <li>Estimation of deleterious elements or other non-grade variables of economic significance (e.g. sulphur for acid mine drainage characterization).</li> <li>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</li> <li>Any assumptions behind modelling of selective mining units.</li> <li>Any assumptions about correlation between variables.</li> <li>Description of how the geological interpretation was used to control the resource estimates.</li> <li>Discussion of basis for using or not using grade cutting or capping.</li> <li>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</li> </ul> | <ul style="list-style-type: none"> <li>Mineralisation is domained based on geological continuity. All domain wireframes are created using Leapfrog software and all subsequent estimation is completed using Datamine software.</li> <li>Lode wireframes are intersected with a validated drill database from which all RAB, AC, Airtrack and erroneous drill holes have been removed. All remaining diamond and RC samples are flagged with a domain identifier and composited to 1m with 0.3m minimum sample. Residual samples are distributed across adjacent component intervals.</li> <li>Composites are analysed for population outliers by domain and are topcut proximal to population disintegration. The top-cut process affects only 1-2% of the data.</li> <li>Some of the principal lodes exhibit bi/multi-model grade populations. These internal populations are controlled by grade indicators based on inflexion points derived from domain log probability plots from which indicator variograms are created. Categorical indicator kriging (CIK) is then used to sub-domain lodes with mixed populations. The block model used in the CIK estimation has blocks set at 1x2x1m to ensure sub-domain complexity is maintained then optimised and re-blocked to the parent block size of 5x5x5m. This model is then used to back flag the composite file with the defined sub-domain identifiers.</li> <li>Variography is created for all domains and sub-domains with sufficient sample data. Output variograms are utilised in kriging neighbourhood analysis (KNA) to generate optimum parent block sizes and estimation parameters.</li> <li>Domains and sub-domains are estimated using ordinary kriging utilising the estimation parameters defined in the KNA as inputs. Grade is estimated into parent blocks only and all kriging quality metrics and search pass values are output. The maximum distance of extrapolation from last known data points for the inferred material is dependent on the geological continuity and confidence across the lode, but less than 40m for the deposit.</li> <li>Search distances are dictated by the range of each individual variogram but typically equate to 1-1.5 times the current 20x20m resource definition spacing. A 3-pass nested search strategy is employed with the first pass always set to the full range of the variogram. The second pass is set at 2 times the variogram range with the final pass set at a factor large enough to ensure all blocks comprising the domain are estimated.</li> <li>The Mineral Resource Estimation is checked against the previous block model estimations following any material update.</li> <li>No assumptions are made regarding the recovery of by-products for this Mineral Resource Estimation.</li> <li>No estimation of deleterious elements or non-grade variables is required.</li> <li>No assumptions have been made regarding the modelling of selective mining units for this Mineral Resource Estimation</li> <li>No assumptions have been made regarding the correlation between variables for this Mineral Resource Estimation.</li> <li>Mineralisation is partitioned into estimation domains relative to stratigraphic position, structural orientation, recorded lithology and specific alteration assemblage. The geological interpretation is initially created from drill data and to be later calibrated with mapping from open pit exposures.</li> <li>Domains are estimated individually with search geometry and variography controlled by lode orientation and grade continuity respectively. Variogram major search directions are aligned with geologically interpreted high grade shoot trends.</li> <li>Categorical indicator kriging has been utilised to define sub-domains in lodes with mixed grade populations to limit the spread of high-grade mineralisation.</li> <li>Dynamic anisotropy has been employed on lodes exhibiting excessive undulation.</li> <li>Boundary analysis has been conducted on key lodes indicating hard boundaries should be maintained across domain and sub-domain contacts.</li> <li>Statistical and visual measures are used to validate the accuracy of the estimation.</li> <li>Volume variance between the wireframe domains and block model domains are assessed.</li> <li>A visual inspection of input composites is compared to the estimated block model in section for each domain.</li> <li>The mean grade of the block model is compared to the naïve and declustered mean grades of the composites by domain with any variance greater than 10% investigated.</li> <li>Swath plots are created by domain and sub-domain in the X, Y, Z, strike and cross strike directions and viewed holistically to vector into any problematic areas.</li> </ul> |
